This is a digital copy of a book that was preserved for generations on library shelves before it was carefully scanned by Google as part of a project to make the world’s books discoverable online.

It has survived long enough for the copyright to expire and the book to enter the public domain. A public domain book is one that was never subject to copyright or whose legal copyright term has expired. Whether a book is in the public domain may vary country to country. Public domain books are our gateways to the past, representing a wealth of history, culture and knowledge that’s often difficult to discover.

Marks, notations and other marginalia present in the original volume will appear in this file - a reminder of this book’s long journey from the publisher to a library and finally to you.

Usage guidelines

Google is proud to partner with libraries to digitize public domain materials and make them widely accessible. Public domain books belong to the public and we are merely their custodians. Nevertheless, this work is expensive, so in order to keep providing this resource, we have taken steps to prevent abuse by commercial parties, including placing technical restrictions on automated querying.

We also ask that you:

+ Make non-commercial use of the files We designed Google Book Search for use by individuals, and we request that you use these files for personal, non-commercial purposes.

+ Refrain from automated querying Do not send automated queries of any sort to Google’s system: If you are conducting research on machine translation, optical character recognition or other areas where access to a large amount of text is helpful, please contact us. We encourage the use of public domain materials for these purposes and may be able to help.

+ Maintain attribution The Google “watermark” you see on each file is essential for informing people about this project and helping them find additional materials through Google Book Search. Please do not remove it.

+ Keep it legal Whatever your use, remember that you are responsible for ensuring that what you are doing is legal. Do not assume that just because we believe a book is in the public domain for users in the United States, that the work is also in the public domain for users in other countries. Whether a book is still in copyright varies from country to country, and we can’t offer guidance on whether any specific use of any specific book is allowed. Please do not assume that a book’s appearance in Google Book Search means it can be used in any manner anywhere in the world. Copyright infringement liability can be quite severe.

About Google Book Search

Google’s mission is to organize the world’s information and to make it universally accessible and useful. Google Book Search helps readers discover the world’s books while helping authors and publishers reach new audiences. You can search through the full text of this book on the web at http://books.google.com/
THE
SECOND SUPPLEMENT
TO THE
PENNY CYCLOPAEDIA
OF
THE SOCIETY
FOR THE
DIFFUSION OF USEFUL KNOWLEDGE.

COMPLETE IN ONE VOLUME.

LONDON:
PUBLISHED BY KNIGHT & CO., 90, FLEET STREET.
MDCCCLVIII.
LONDON:
BRADBURY AND EVANS, PRINTERS, WHITEFRIARS.
NOTICE.

THE FIRST SUPPLEMENT of the 'Penny Cyclopædia,' in Two Volumes, was published in 1846. THE SECOND SUPPLEMENT, now completed in One Volume, follows the same plan as that of the original Work, comprising under one Alphabetical Arrangement, the accumulated information of the twelve years which have elapsed since the publication of the First Supplement. A limited number only of this Volume has been printed; and it will not be kept on sale after that number has been disposed of.

CHARLES KNIGHT.

May 28, 1858.
SECOND SUPPLEMENT
OF
THE PENNY CYCLOPAEDIA
OF
THE SOCIETY FOR THE DIFFUSION OF
USEFUL KNOWLEDGE.

(After the abridgment & 1, in the references and elsewhere, refers to the First Supplement; § 2, to the present Second Supplement. The references without either of these additions are to the 'Penny Cyclopaedia' as distinct from the two Supplements.)

ABATÉMENT. Pleas in abatement for misnomer have been abolished (3 & 4 Will. IV. c. 42), and an objection thus taken to the nonjoinder or misjoinder of parties is no longer of any avail in a civil action, the courts having now express powers of amendment. (Common Law Procedure Act, 1852.) A similar observation applies to pleas in abatement to an indictment or information. (14 & 15 Vict. c. 106)

ABEY HOLME. [CUMBRIA.]
ABBEYLEIX. [QUEEN'S COUNTY.]
ABBOTS BROMLEY. [STAFFORDSHIRE.]

ABEKAHKTUH, a large walled town, on the west bank of the river Agonee, which separates it from the kingdom of Dahomey, about 60 miles inland from Lagos, in the Right of Benin, and about 160 miles from Abomey, the capital of Dahomey. It is in the petty kingdom of Egba, which is subdiy to Yorrobi, but the town itself, which has sprung up within the last forty years, is independent, and is governed by a chief who is not a king. The inhabitants amount to upwards of 50,000, and are composed of the natives of Egba, a great number of liberated blacks, many of them from Sierra Leone, and several missionaries, who report that their lives have been highly successful. The King of Dahomey is more than once attacked the town in vain. In 1848 one of his Amazonian regiments was almost entirely destroyed by the Abekahktuhs in one of these attempts. In June, 1856, when Captain E. E. Forbes and Mr. Becroft were at Abomey, Mr. Becroft was told by the King himself to warn the missionaries to withdraw, as he was going to make war upon the town, when it was explained to him that the town was in alliance with Great Britain, and that there were great numbers of free negroes and several missionaries there. Nevertheless, he invaded their territory at the head of a large hostile force, a great part consisting of Amazons, and met with a severe defeat under its walls, on March 3rd, 1856, which is said to have greatly crippled his power. The town of Abekahktu, which means 'under the stone,' has reference to a large natural cave within the town walls, wherein the market is held. A new species of silk from Bouma in the interior, and a peculiar description of wool, from Quota to the westward of Abekahktu, have been introduced as articles of trade into England, and are likely to prove valuable.

ABECKETT, GILBERT ABBOTT, born in Golden-square, London, in the year 1810, was the son of a respectable merchant, and was educated at Westminster School. He very early displayed great talent as a humourist. As early as 1825, his own dramatic productions, in prose and verse, but all in burlesque character, were published in Duncombe's 'British Theatre;' in 1828-29 nine more appeared in Cummeland's 'British Theatre;' and in 1837 four others were printed in Webster's 'Acting Drama,' most of which had attained some success on the stage. In 1843 he produced 'The Mirror, or Hall of Statues,' a musical burlesque. In connection with the drama, also, he published in 1844 'Scenes from the Rejected Comedies by some of the Competitors for the Prize offered by Mr. Webster.' These 'Scenes' were a series of parodies upon living dramatists (including one of himself), which had appeared in 'Punch' previous to their publication in a separate form. In 1846 he published 'The Quizzology of the British Drama.' In conjunction with his schoolfellow, Mr. Henry Mayhew, he started several comic periodical works, of which 'Figaro in London,' begun about 1830, was undoubtedly the precursor of 'Punch.' When that work had swallowed up its rivals, Mr. A. Beckett became a constant contributor to it, and the adventures, the epistles, and anecdotes of Mr. Dunup were among the most laughable morsels of that publication. He took a pride in the work, and it was his boast that, till the period of his death, no number appeared without something, however small, from his pen. His humour was without malice, and displayed a varied reading, with considerable knowledge of the law. In the midst of his exhibitions of fancy he had not neglected the more serious studies of his profession. He was trained as a lawyer; and in March 1846 his reputation induced Mr. Charles Buller to intrust to him the investigation of the iniquities practised in the Andover Union workhouse. This he conducted in a satisfactory manner, and in his report he displayed a clear and solid judgment in sober and well-chosen language. Some leaders in 'The Times' on the same subject have been also attributed to him. He had previously been an occasional contributor to that journal. His conduct of the Andover inquiry led to his appointment in 1849 as magistrate of the police-court of Greenwich and Woolwich, whence he was removed in 1850 to that of Southwark—positions which he held in an irreproachable manner. Besides an edition of 'The Small Debts Act, with Annotations and Explanations,' published in 1846, he produced the 'Comic Blackstone,' which was published in 1844-46; a 'Comic History of England,' published in monthly parts, forming a volume completed in 1848; and a 'Comic History of Rome,' also in monthly parts, completed in 1852. He likewise, in 1845, edited George Cruikshank's 'Table Book.' After a very short illness he died at Bonogleghe, on the 26th of April 1866.

ABERAVON. [Glamorganshire.]
ABERAYRON. [Cardiganshire.]
ABERDAH. [Glamorganshire.]
ABERNETHY. [Perthshire.]
ABORTION, a term used in Botany and Horticulture. In Botany, Abortion is employed to express the absence of an organ in relation to an ideal type. Thus the flowers of
Sorophorariaeae and Lamiaeae have their sepals and petals arranged in the num-b-r five. According to a very general law, one stamen equals in number the petals and sepals, but in this case they do not. In the majority of instances the stamens are but four; hence it is said that one stamen is aborted, or there is an abortion of one stamen. The want of harmony between the parts of the flower generally is thus spoken of. In other instances when the stamens are numerous, and the seeds only one, two, or three, the remaining ovules are aborted.

In horticulture, the premature development of the fruit, or any defect in it, is called Abortion.

ABRAXAS, a genus of Nocturnal Lepidoptera, to which belongs the common Magpie Moth, A. grandulatia. The caterpillar of this moth attacks the leaves of gooseberry and currant bushes at the beginning of the summer. It is of a yellowish-white colour, with an orange stripe on each side, and covered with black spots. The chrysalis is black, relieved at its pointed end with orange circles. The expanded fore-wings of the perfect insect measure about one inch and a half across. The wings are of a yellowish-white colour, variously spotted with black. The fore-wings have a band of pale orange. The body is orange, spotted with black. The eggs are deposited on currant or gooseberry leaves in July or August, and the caterpillars are hatched in September. To the fore-wings of these caterpillars they may be picked off, or dusted with the powder of white heliolebe, or the leaves of the plants attacked may be burned.

ABROMA (from a & Broma, 'not fit for food,' in opposition to theodroma, 'food for gods'), a genus of plants belonging to the family Papilionaceae. The species composition of small trees, with hairy lobed leaves and extra-axillary or terminal few-flowered peduncles at the tops of the branches. *Abroma augusta* is a handsome tree, with drooping purple flowers, and has the peduncles opposite the leaves. It is a native of the East Indies. The fibrous tissue of the bark of this plant is manufactured into cordage.

ABRUS (from a & Brous, soft), a genus of plants belonging to the papilionaceous division of the order Leguminosae. The calyx is greenish with the upper expanded, and is a legume oblong, compressed, and 4-5-seeded. There is but one species, *A. precatorius*, which is a delicate twining shrub, with abruptly pinnate leaves, bearing many pairs of leaflets. It is a native of the East Indies, but is also found in the tropical part of Africa and America, where perhaps it has been introduced. The seeds of the commoner variety are red, with a black spot, whilst various varieties produce various coloured seeds. These seeds are in much request as ornaments among those of the cultivated garden where they are struck as beads, with shells, and other hard seeds. They are brought to Europe from Guinea and the East and West Indies. They are used frequently as beads for rosaries; hence the name *precatorius* given to this species. The leaves and flowers are also used in the West Indies for secretaries which characterises the liquorice plant (*Oligyryxa glabra*). In the West Indies it is called Wild Liquorice, and used for the same purposes as the common liquorice. The seeds have been accused of possessing narcotic properties, but this is an error. When swallowed they are very digestive.

ABSINTHINE. [Chemistry, S. 2.]

ABUTTIONS. [Chemistry, S. 2.]

ACERAS, a genus of Orchidaceae Plants, of which one species is found growing in Great Britain. It is a small plant, from 8 to 12 inches in height. It has a long lax spike of greenish-yellow flowers, the parts of which are so arranged as to give them the appearance of the small figure of a man: hence this plant has been called the *man-in-the-hand*.

ACETAL. [Chemistry, S. 1.]

ACETONE. [Chemistry, S. 1.]

ACETONITRILE. [Chemistry, S. 2.]

ACHILL, an island off the west coast of the barony of Burrisboole in the county of Mayo, in Ireland. With the adjoining peninsula of Corraun Achill it constitutes the parish of Achill, and one electoral division of the Poar-Law county of Mayo. It is separated from the coast of Europe by a narrow arm of the sea, called Achill Sound, connecting Clew Bay with Blackwood Harbour. The length from Achill Beg island at the extremity of the Sound, on the south, to Achill Head, at the Atlantic extremity of the island on the west, is 152 miles, breadth from north to south, 8 miles, elevation of the south side to Ridge Point in Blackwood Bay on the north, 192 miles. It lies between 53° 51' and 54° 0' N. lat., and 5° 55' and 10° 15' W. long. The area is 33,268 acres. The population of Achill is about 4000 persons.

The island, the name of which signifies ' Eagle,' is in form nearly a right-angled triangle, of which one side extends from south to north, facing the mainland, from Achill Beg to Ridge Point; another from east to west, from Ridge Point to Blackwood Harbour; and the third side, forming a re-entrant irregular coastal-line of about 35 miles, and having the Bay of Tramore about midway, is washed by the Atlantic. The surface, which is excessively wild, barren, and boggy, rises towards the north and west into mountains of 2000 feet and upwards; and at one point near the western extremity of the island, Toucraghannah, the cliff towards Blackwood Bay descends precipitously from the highest point of the island, forming a shelving face of rock, of the extraordinary height of 2928 feet. Achill Head, at the extreme west, consists of a narrow ridge of rock, of about a mile in length, and from 300 to 400 feet in height, the summit of which is in some places but a few yards in width. The coast on the south-western side is also very precipitous: the cliff at Doeega Head, which forms the eastern boundary of Tramore Bay, rises 813 feet over the Atlantic, and is nearly perpendicular. The geological structure of the island is simple; the whole being a mass of mica slate.

ACCRINGTON, Lancashire, a manufacturing town of recent growth, in the parish of Whalley and higher division of Blackburn hundred, is situated in a deep valley surrounded by hills on the banks of the Hindburn, or Accrington brook, in 53° 45' N. lat., 2° 22' W. long, distant 19 miles N. from Manchester, 207 miles N.W. by N. from London by road, and 225 miles by the railways to East and West Lancashire Railways. The population of the town in 1851 was 7481. The livings are perpetual curacies in the archdeaconry and diocese of Manchester.

ACCRUING possesses two churches of the Establishment: one, on the castle, is a plate building; the other, Christ Church, is a spacious gothic edifice erected in 1833, at an expense of about 8000£. The Wesleyan Methodists, Independents, Baptists, Roman Catholics, and Swedish- gians have places of worship. There are national schools, and the parish church has one of the S. E. parsonage rooms. The town is paved, lighted with gas, and well supplied with water. The general aspect of the town is good, and the inhabitants claim for it the distinction of being the cleanest town in Lancashire. It requires, however, many sanitary improvements, especially in the smaller streets and lanes.

The drainage is very defective. Accrington is considered to be the centre of the cotton-printing business. There are two large print works, employing upwards of 150 persons, and extensive bleaching works. The neighbouring coal-mines employ many of the inhabitants.
achly a genus of Cryptogamons Plant, belonging to the order Gomeraea. The species of this genus are very numerous, and, although not useful, they are of many extensively cultivated, on account of the beauty of their flowers. In consequence of their general color, a great many varieties of the species are becoming known. After flowering, the stems die down; and the tubers should be dug up, and kept free from frost and wet till January, when, by planting them in succession, flowers may be obtained till the summer. They may be planted in a mixture of loam and leaf-mold, with a little silver sand. They can be placed out in the summer, but require shading at hot days.

ACHLYA, a genus of Cryptogamons Plant, belonging to the order Gomeraea. It is a genus of a single species, which expands at the end into a large cell, which is cut off from the lower portion of the tube by the formation of a partition. In this enlarged cell a circulation of granular particles has been observed. In the course of time these cells have become larger and larger, and the tube of the plant eventually bursts at some spot, and allows of the escape of the enclosed cells; but before this takes place the cells in the interior move about, and, after their escape, exhibit for a considerable time an active movement. They are good examples of the Zoophyta. The column attaches itself to some fitting object, and grows into little plants, like their preceeding. A similar process goes on in most of the Algae, but not so easily observed as in this case.

principal apartments open. Beyond this patio there is another, round which the private apartments are built, and beyond this another, where the parade, kitchen, servants' rooms. The patios are frequently roofed over with treliss-work, along which vines are trained to grow; and when water is abundant there is a pond or a jet-d'eau, or both, in the centre. To go from one part of the house to another, without leaving the main building, or passing the Plaza, and the Alameda, during the hours when they are frequented, are the chief sources of amusement and gratification, and this they often afford in a high degree; as during the hours of recreation in the evening the whole population, rich and poor, flock thither, with the exception of the very old or very young, who however indemnify themselves by enjoying the fresh air on the flat roofs of the houses. San-Felipe-de-Aconcagua, the capital of the province, situated on the right bank of the river Aconcagua, at a distance of 20 miles from Santiago, the capital of Chili, and the same distance W., by S. from the Peak of Aconcagua, has about 13,000 inhabitants. Santa-Rosa, 20 miles higher up the river, and E.S.E., of San-Felipe, has a population of 6000. Petorca, situated 33 miles W. from Santiago, and in the same mining district of the province, is a small place, with hardly more than 1000 inhabitants.

The road from Santiago to San-Felipe crosses the range of hills called Cuesta-de-Cachabuco at the height of 2000 feet above the sea, and is continued northward through Petorca to La Serena. Another road leads down the valley of the Aconcagua through Quillota to Valparaiso, distant about 60 miles. The communication with the Argentine Provinces is kept up by the road over the Andes by the Aconcagua, and across the Andes by the Pass of La Cumbre (12,464 feet above the sea) through Uspallata to Mendoza. Another road, branching off from the northern road at the village of San-Antonio, about 10 miles N. from San-Felipe, and running up the left bank of the Putaendo, crosses the Andes by the Pato Pass, and leads to the Argentine town and province of San-Juan. The road by the Cumbre Pass is open for mules from November to the end of May; for the rest of the year it is closed to all but foot-passengers, and the journey is then made by the dangerous Pass of the Pato Pass that General San Martin marched over the Andes into Chili with the army of Buenos Ayres in 1817.

(Miera, Travels in Chili and La Plata : Meyen's Reise in das Amazonenflusse ; Travels and Adventures in the Plata and Amazonerflusse ; Paris, Buenos Ayres and the Provinces of La Plata ; Surveying Voyages of the Adventure and Beagle.)

ACONITINA. [CHEMISTRY. S. I.]

ACORINE, ACORIDEE, or ACORACEAE, a small natural order of Endogens, with the following essential character:—The flowers are hermaphrodite, surrounded with scales. The spathe is leaf-like, but not rolled up. The stamens are complete, placed opposite the scales, and have two-celled anthers which are turnedit inward. The ovary is distinct. The fruit is baccate, juicy at first, but finally juicyless. The seeds have the embryo seated in the axis of a copious alburnum. The rootstock is jointed; the leaves sword-shaped, and embracing each other in the bud. Such is the character given this order, which was first separated from Arecaceae by Agardh, and the separation was afterwards adopted by Schott, Link, and Lindley. The genera assigned to this order by Lindley were Acorus, Gymnostachys, Tapistrum, and Aegiphila. The two last genera are now assigned by the author must be regarded as a small group of plants in its geographical distribution is confined to the eastern hemisphere. None of them have the acrid properties of some of the Arecaceae. The Acorus Calamus is a British plant, a common vegetable, having small rhizomes, which when dried, are much used in medicine as a stomachic remedy. ACORINE (from Acorus, indistinct), a division of the class Radiata, adopted by Owen, and applied to the Alcaceae, the Polysperma, except the Bryoxoa, the Polyspasia, and certain forms of Eriocaulon, in some of which are the indications of a nervous system decided, and they constitute the lowest forms of the Radiate group of animals.
ADDITIONS.

ADDITIONS DISEASE. [MEDICINE. & 2.] ADMINISTRATION AND ADMINISTRATOR. The whole jurisdiction of the Ecclesiastical Courts in the grant and withdrawal of administrations, and the superintendence of administrators, has been transferred to the Court of Probate. (20 & 21 Vict. c. 77. [PROBATE, Court of, & 2.]) The customs of Loundon, 1696, (I. C. vol. i. p. 120) have been abolished, and the distribution of the estates of intestates that were previously ordered throughout England. (19 & 20 Vict. c. 94; 'Blackstone's Comm.', Mr. Kerr's ed., vol. ii. p. 564.)

ADMIRALTY, COURT OF. The jurisdiction of this Court has been extended, and a ship's, an action, and a writ of peculiar jurisdiction, c. 89 & 10 Vict. c. 96. Questions relating to the action and capture of ships may also be determined by this Court or the Vice Admiralty Courts abroad. (13 & 14 Vict. c. 92.)

ADOLPHUS, JOHN, was born in 1770 and died July 17, 1845. Mr. Adolphus was a barrister of high standing in the criminal courts, and at his decease was father of the Old Bailey bar. He was a keen advocate, a fluent speaker, and a good lawyer. His practice, previously very considerable, was highly increased by the manner in which he distinguished himself as leading counsel for Thistlewood and the other prisoners charged with a treasonable conspiracy in 1820, though he was retained on their behalf only a few hours before they were hanged. Mr. Adolphus is best known as the author of the 'History of England from the Accession of George III.', originally published in 3 volumes in 1805, but which he subsequently revised and greatly extended. Of this enlarged edition the seventh volume appeared in 1839. The life of the author was a long one, and the conclusion has not been published. It is a work of considerable research and very carefully executed, but it does not exhibit very high historical powers. He was also the author of 'Biographical Memoirs of the French Revolution'; 'Political State of the British Empire', 4 vol. 1818; 'Memoirs of John Banister'; and some fugitive pieces and pamphlets.

ADULTERY. The action of damages for criminal conversation is now supported by the Act of 1854, 5 & 6 Vict. c. 17, creating the 'Court for Divorce and Matrimonial Causes.' The injured husband, in applying to this Court for a divorce or a judicial separation, may claim damages, which however can only be awarded to him by the verdict of a jury, and the Court may then direct in what manner the damages are to be disposed of; for the whole or any part thereof may be settled on the children of the marriage, or as a provision for the maintenance of the wife. [DISSORCE, § 2; SEPARATION, JUDICIAR, § 2; HUSBAND AND WIFE, § 2.]

Ag a genus of plants belonging to the order Umbellifere. One species, _A. podagracia_, is common throughout the whole of Europe, and grows abundantly in Great Britain. It has a stem one or two feet high, with furrows. The leaves are two or three forked, and the entire fruit is covered with a net-like veil, having the acutely serrate. It has a creeping root, and grows in damp places. Although well known, and having the names of Goat-Weed, Ash-Weed, Herb Gerard, and Wild Masterwort, it seems to possess no medicinal properties. Linnaeus says that it is boiled when young, and eaten as greens in Sweden.

ETHERS, SILICIC. [CHEMISTRY, § 1.]

AFFIRMATION (in Law). Every person who has conscientious objections to taking an oath, may owe to be permitted to make a solemn affirmation in lieu thereof, the effect of which is the same as if the testimony were given oath. (Common Law Procedure Act, 1854.)

AFFRE, DENIS AUGUSTE, archbishop of Paris, was born at St.-Borne, in the department of Tarn, Sept. 27, 1793. At the age of 18, he entered the seminary of St. Sulpice, and in 1818, was ordained priest, and discharged a variety of ecclesiastical functions till he became archbishop of Paris in 1851. Although a man of great studious learning, and the author of various treatises (among which was one on Egyptian hieroglyphics), he would scarcely have found a place in the history of his times, but for the lamentable circumstances of his death on the 27th June, 1848. Paris was then in a state of commotion through the news that the archbishop had been garrisoned with a vast body of insurgents. The archbishop was induced to apply to General Cavaignac, proposing to stand between the contending bodies as a messenger of peace. The general told him that the course was full of danger. 'My life,' he replied, 'is of small consequence.' Some hours afterwards the firing of the soldiery having ceased at his desire, the archbishop mounted a barricade erected at the entrance of the Rue Penthievre, where he was killed. He was a national garde, wearing a workman's dress, carrying in his hand a green branch as an emblem of peace; and he had at his side a faithful servant named Pierre Sellier. The devoted ecclesiastic was not received with the confidence that he expected to inspire. Some of the insurgents thrust out their hands, but others remained silent, while others groaned and hooted. The prelate endeavoured to speak a few words; but the insurgents, fancying themselves betrayed, seized him, and threw him on his back, and that they would avenge him. 'No, no, my friends,' he replied; 'there has been blood enough shed; let mine be the last that is spilt.' He was carried to the archiepiscopal palace, and died the same day. The National Assembly issued a decree announcing a profound grief at the event of his death, and his public funeral took place on the 7th of July, amidst the deepest feelings of popular regret. (Nouvelle Biographie Universelle, 1832.)

AFREEDIA KHAN, or Afrared, sometimes spoken of under the more general name of Kyber or inhabit the Kyber hills on the confines of Cabul and the Panjab. They command the passes in these hills, for a safe conduct through which their Maliks, or chiefs, consider themselves entitled to demand a toll for the men and mules that pass through them. Now, however, they were formerly paid by the rulers of Cabul, and the non-payment of it after the restoration of Shah Soojah to the throne excited the furious hostility of the Afreedia against the British and their auxiliaries. They resisted the march of Colonel Wade and the other columns through the passes in July, 1839, but were compelled to evacuate the fort, Ali-Musjid, the key of the pass, which, with other posts between Pesahwar and Jellalabad, was garrisoned by small detached parties. At a subsequent period of the Afghan war, January 19, 1849, they defended two Scapes under Brigadier Wild from Pesahwar to the relief of two other Sepoy regiments under Colonel Moseley in Ali-Musjid, which had seized that fort some days before, and had been robbed of their provisions on their way. Cut off from all communication with the brigadier, and short of provision, Moseley evacuated the fort on the 24th, which was immediately seized by the Afreedia. On General Pollock's advance from Pesahwar to the relief of Jellalabad, in the spring of 1842, the Afreedio came out to meet him, and left him with cavalry and Dhaka for 50,000 rupees; but Pollock chose to force his way, sweeping the heights on each side of the defile with his light troops, whilst the main body advanced through the pass, having demolished the barrier raised by the enemy. When they crossed the entire range, it was found the Afreedia had evacuated it; they then held by a strong force till the final withdrawal of the British troops from Afghanistan, when it was blown up. We next hear of the Afreedia in connection with another pass on the road from Pesahwar to Kohat, leading to the Salt Range. On February 2, 1850, about 1000 Afreedia plundered the camp of a party of British Sappers employed in making a road through this pass, about 32 miles south from Pesahwar, and killed several of the men. To avenge this massacre a strong force, under Colonel Bradshaw, stormed the hills in the neighbourhood, destroying six villages and a great number of the enemy, who however made some resistance on the return of the troops through the passes.

To the west of the Kyber hills, on the Cabul side, the Momand clan dwells along the banks of the Cabul river. Their chief place, Lalpoorab, the residence of the Malik, is opposite Daka. 

AFRICA. At the period when the article Africa in the 'Penny Cyclopaedia' was written, the descent of the Quorra, or Neger, had recently been accomplished by the brothers Richard and John Lander. In a subsequent article, Quorra, additional details are given respecting the river and the present state of the country. The Quorra is said to have been reduced to the year 1840. At that time an expedition was in preparation by the British government, the object of which was to check and supersede the foreign trade in slaves by the establishment of a commerce along the banks of the Quorra, which should be more beneficial to the native chiefs.
than the cruel traffic in slaves. This expedition, consisting of three steam-vessels, began the ascent of the river in 1841, but was compelled to abandon it, it being impossible to seize all the tributaries. When the river was attempted again in 1843, the expedition, consisting of three vessels, was under the command of Captain Young, who, in March 1844, ascended the river to the latitude of 14° 20' S., where they were forced to return by the want of provisions. The next attempt was made in the years 1846 and 1847, under the command of Captain Young, who ascended the river to the latitude of 17° 20' S., but was compelled to return to the coast.

The next attempt to ascend the river was made in the summer of 1848, under the command of Captain Young, who ascended the river to the latitude of 20° 30' S., and the expedition was again returned to the coast by the want of provisions. The next attempt was made in the summer of 1849, under the command of Captain Young, who ascended the river to the latitude of 25° 30' S., but was compelled to return to the coast by the same cause.

The next attempt was made in the summer of 1850, under the command of Captain Young, who ascended the river to the latitude of 30° 30' S., but was compelled to return to the coast by the same cause. The next attempt was made in the summer of 1851, under the command of Captain Young, who ascended the river to the latitude of 35° 30' S., but was compelled to return to the coast by the same cause.

The next attempt was made in the summer of 1852, under the command of Captain Young, who ascended the river to the latitude of 40° 30' S., but was compelled to return to the coast by the same cause. The next attempt was made in the summer of 1853, under the command of Captain Young, who ascended the river to the latitude of 45° 30' S., but was compelled to return to the coast by the same cause.

The next attempt was made in the summer of 1854, under the command of Captain Young, who ascended the river to the latitude of 50° 30' S., but was compelled to return to the coast by the same cause. The next attempt was made in the summer of 1855, under the command of Captain Young, who ascended the river to the latitude of 55° 30' S., but was compelled to return to the coast by the same cause.

The next attempt was made in the summer of 1856, under the command of Captain Young, who ascended the river to the latitude of 60° 30' S., but was compelled to return to the coast by the same cause. The next attempt was made in the summer of 1857, under the command of Captain Young, who ascended the river to the latitude of 65° 30' S., but was compelled to return to the coast by the same cause.

The next attempt was made in the summer of 1858, under the command of Captain Young, who ascended the river to the latitude of 70° 30' S., but was compelled to return to the coast by the same cause. The next attempt was made in the summer of 1859, under the command of Captain Young, who ascended the river to the latitude of 75° 30' S., but was compelled to return to the coast by the same cause.

The next attempt was made in the summer of 1860, under the command of Captain Young, who ascended the river to the latitude of 80° 30' S., but was compelled to return to the coast by the same cause. The next attempt was made in the summer of 1861, under the command of Captain Young, who ascended the river to the latitude of 85° 30' S., but was compelled to return to the coast by the same cause.

The next attempt was made in the summer of 1862, under the command of Captain Young, who ascended the river to the latitude of 90° 30' S., but was compelled to return to the coast by the same cause. The next attempt was made in the summer of 1863, under the command of Captain Young, who ascended the river to the latitude of 95° 30' S., but was compelled to return to the coast by the same cause.

The next attempt was made in the summer of 1864, under the command of Captain Young, who ascended the river to the latitude of 100° 30' S., but was compelled to return to the coast by the same cause. The next attempt was made in the summer of 1865, under the command of Captain Young, who ascended the river to the latitude of 105° 30' S., but was compelled to return to the coast by the same cause.

The next attempt was made in the summer of 1866, under the command of Captain Young, who ascended the river to the latitude of 110° 30' S., but was compelled to return to the coast by the same cause. The next attempt was made in the summer of 1867, under the command of Captain Young, who ascended the river to the latitude of 115° 30' S., but was compelled to return to the coast by the same cause.

The next attempt was made in the summer of 1868, under the command of Captain Young, who ascended the river to the latitude of 120° 30' S., but was compelled to return to the coast by the same cause. The next attempt was made in the summer of 1869, under the command of Captain Young, who ascended the river to the latitude of 125° 30' S., but was compelled to return to the coast by the same cause.

The next attempt was made in the summer of 1870, under the command of Captain Young, who ascended the river to the latitude of 130° 30' S., but was compelled to return to the coast by the same cause. The next attempt was made in the summer of 1871, under the command of Captain Young, who ascended the river to the latitude of 135° 30' S., but was compelled to return to the coast by the same cause.

The next attempt was made in the summer of 1872, under the command of Captain Young, who ascended the river to the latitude of 140° 30' S., but was compelled to return to the coast by the same cause. The next attempt was made in the summer of 1873, under the command of Captain Young, who ascended the river to the latitude of 145° 30' S., but was compelled to return to the coast by the same cause.

The next attempt was made in the summer of 1874, under the command of Captain Young, who ascended the river to the latitude of 150° 30' S., but was compelled to return to the coast by the same cause. The next attempt was made in the summer of 1875, under the command of Captain Young, who ascended the river to the latitude of 155° 30' S., but was compelled to return to the coast by the same cause.

The next attempt was made in the summer of 1876, under the command of Captain Young, who ascended the river to the latitude of 160° 30' S., but was compelled to return to the coast by the same cause. The next attempt was made in the summer of 1877, under the command of Captain Young, who ascended the river to the latitude of 165° 30' S., but was compelled to return to the coast by the same cause.

The next attempt was made in the summer of 1878, under the command of Captain Young, who ascended the river to the latitude of 170° 30' S., but was compelled to return to the coast by the same cause. The next attempt was made in the summer of 1879, under the command of Captain Young, who ascended the river to the latitude of 175° 30' S., but was compelled to return to the coast by the same cause.

The next attempt was made in the summer of 1880, under the command of Captain Young, who ascended the river to the latitude of 180° 30' S., but was compelled to return to the coast by the same cause. The next attempt was made in the summer of 1881, under the command of Captain Young, who ascended the river to the latitude of 185° 30' S., but was compelled to return to the coast by the same cause.

The next attempt was made in the summer of 1882, under the command of Captain Young, who ascended the river to the latitude of 190° 30' S., but was compelled to return to the coast by the same cause. The next attempt was made in the summer of 1883, under the command of Captain Young, who ascended the river to the latitude of 195° 30' S., but was compelled to return to the coast by the same cause.

The next attempt was made in the summer of 1884, under the command of Captain Young, who ascended the river to the latitude of 200° 30' S., but was compelled to return to the coast by the same cause. The next attempt was made in the summer of 1885, under the command of Captain Young, who ascended the river to the latitude of 205° 30' S., but was compelled to return to the coast by the same cause.

The next attempt was made in the summer of 1886, under the command of Captain Young, who ascended the river to the latitude of 210° 30' S., but was compelled to return to the coast by the same cause. The next attempt was made in the summer of 1887, under the command of Captain Young, who ascended the river to the latitude of 215° 30' S., but was compelled to return to the coast by the same cause.
Anderson have each published a volume giving an account of their travels. We will now give an account of the missionary explorations from the eastern coast, and of the expedition to Central Africa.

The seafaring and enterprising missionaries, Kræf and Rebmann, stationed at Rabiah and Tripoli, in about 1847, began their journeys into the interior of the continent. In that year Mr. Rebmann penetrated westward to Teita, a "country whose mountains rise to such a height out of the vast surrounding plains, that even eminences near Rabiah are to be seen at a distance of 20 miles, and with a magnifying glass you could distinguish the same missionary a journey farther into the interior, to the still more elevated country of Djagg, where, at a distance of rather more than 20 geographical miles from the coast, in a direction about W.N.W. from Tripoli, he made the remarkable discovery of a lofty mountain, named Kilimandjaro, of which the summit is covered with perpetual snow. The existence of snow on Kilimandjaro has been disputed in Europe, though it is difficult to say on what reasonable ground. In subsequent journeys, both Mr. Rebmann and his colleague Dr. Kræf satisfied themselves of the fact; and unless it be intended absolutely to impugn their veracity, their evidence cannot be rejected. In April, 1849, he again set out on his way into the interior, but was prevented by a more considerable indication of the snow during November and December of the same year. Dr. Kræf successfully penetrated as far as Ukambani, a country situated northward of Djagg. Of the geographical results of this journey, one of the most important is the discovery of another snowy mountain, named Kilimanjaro, for Mr. and Mrs. Rebmann. Kilimanjaro. Kénia, is thus described by Dr. Kræf:—"The sky being clear, I got a full sight of the snow mountain... It appeared to be like a gigantic wall, whose summit I observed covered with two immense towers, two horns as you may call them, which were, however, at a considerable distance from each other, give the mountain a grand and majestic appearance, which raised in my mind overwhelming feelings. Kilimandjaro in Djagg has a dome-like summit; but in Kénia above are two cones of the mountain; two horns rise like two mighty pillars, which I have no doubt are seen by the inhabitants of the countries bordering on the northern latitudes of the equator. Still less do I doubt that the volume of water which Kénia issues to the north runs towards the basin of the White Nile." Rebmann's map (Church Missionary Intelligence) Kénia is placed in 1° S. lat., 35° 10' E. long., at a distance of 320 geographical miles north and 55 west from Tripoli. This position, however, can only be considered as a rough approximation, inasmuch as the name of Kræf, in the same latitude, the country of Ukambani and the river Dana, as the upper course of the Orib is called. On this journey the enterprising traveller was subjected to the greatest hardships and sufferings. The climate is so arid, so barren, that fresh discoveries were made in this journey, but some further information was collected respecting the river which flows from the Kénia (Nudukenia or Kirenia) northward, and forms most probably one of the head-waters of the Nile.

The expedition to Northern and Central Africa, conducted by Mr. Richardson, accompanied by Drs. Barth and Overweg, is one of great importance. This expedition originated with Mr. Richardson, who, after having returned from his travels in the northern portion of the Sahara in 1845 and 1846, invited Mr. Dr. Barth, to accompany him in the purpose of concluding commercial treaties with the chiefs of the desert-regions between Tripoli and Lake Chad. Through the lively interest taken in it by Chevalier Bunsen, Baron Humboldt, and Professor Ritter, it was arranged that Dr. Barth and Dr. Overweg, two Germans, should accompany Mr. Richardson for the purpose of making scientific observations. Lord Palmerston sanctioned this proposal, and afforded the two travellers pecuniary assistance, in addition to the knowledge and information obtained through the Geographical Society in Berlin and the King of Prussia.

The three travellers departed from this country at the latter end of 1849, and arrived in Tripoli in the beginning of the following year. Previously to starting from that place, they had been induced to the idea of the two Germans, and surveyed by the two Germans within a radius of 60 to 80 miles from the town, Tripoli. An unexpected degree of cold was experienced in these excursions. On one day the thermometer, before sunrise, stood as low as 60° Fahrenheit, and on the 2nd and 3rd of February, the snow obliged the travellers to remain in their tents. After their return from Tripoli, several were required for their preparations; and the transport of a boat for navigating Lake Chad caused considerable difficulty. For this purpose a beautiful wherry had been constructed by the direction of the admiral at Malta, broad in the beam, and very light on water; but it was necessary to take it to pieces, and several canoes were requisite to convey it across the burning sands of the Sahara.

The travellers started at last on the 24th of March, 1850, the great caravan having departed before them; but the party formed a small caravan of itself, having about 40 camels and men. Every possible assistance was rendered by her Majesty's consuls in Tripoli and Murzuk to the undertakings, so that the expedition started under the most favorable circumstances.

The direction of the route to Murzuk was almost due south from Tripoli, beyond the Gharian defile, the country consisting of a continuous table-land, of an average elevation of 2000 feet. As far as the well of Tobabynia, many deep wells intersect this table-land, and the rains of several Roman monuments and cisterns were discovered by the travellers. Southward of that place is a table-land, or Hamadah, an immense desert of considerably greater elevation, and extending for about 110 geographical miles in the same direction. As far as the eye can reach, neither trees nor buildings are visible; and it is an apparent fact which occurs only is found scattered in the trifling irregularities of the surface. The ground is covered with small stones, pyramids of sand, which, erected with great labour, serve as road-marks to the intrepid camel-drivers by day, while the polar sun has set. On the 24th of February the party travelled six days the expedition reached the southern edge of this table-land, which descends in perpendicular walls to the Wadjel El Has. Following the descent for about 40 geographical miles the travellers came to the Waddi Shikait, a valley, over another plateau of equally dismal aspect. It is composed of a black sandstone, the disintegration of which forms a dark yellow sand, covering the inequalities of the stony surface, from which stands out prominently the black rock, in high, opposite contrast for the bare, yellow desert sandstone and basaltic rocks. They reached Murzuk on the 6th of May, and remained there till the 13th of June, collecting much important information respecting the countries and nations to the south. Murzuk is very unhealthy and dangerous for Europeans and Europeans, but happily none of the party suffered during their stay.

On the 13th of June they set off for Ghat, which they reached on the 18th of July. The most interesting result of this journey was the discovery of several curious sculptures on the rocks of the surrounding country, consisting of two human figures with the heads of birds, and a bull, armed with spears, shields, and arrows, and fighting for a child; the other is a fine herd of oxen going to a watering-place, and another. It is said that the two figures of the travellers the two works bear a striking and unmistakable resemblance to the sculptures of Egypt. They are evidently of much higher antiquity than many other sculptured tablets found by the travellers, on which camels formed generally the principal objects.

The party started from Ghat, after a stay of some days, for the kingdom of Al or Asben. They had to cross a vast desert, totally uninhabited, for about 250 geographical miles, and succeeded in reaching Taghajit, the first inhabited place in this desert.

The route from Ghat to Al or Air is described by Dr. Overweg as a mountain-path leading over ridges, table-lands, and deep-cut rocky valleys. Wherever the wadis become broader, and through the agency of rain are covered with disintegrated sandstone and sand, the most peculiar and scarce vegetation is seen. In this corner of the country the character of the country is here of much greater interest. From Murzuk to Ghat, and farther to the south, the prevailing formation consists of sandstone and sand-stone, through which a coil spring, with all the aspect of the rocks, the same slopes of the mountains and intersections of the valleys, and the same horizontal strata. At Aggeri, about 70 miles to the south of Ghat, the entire scene suddenly changes. The mountains are now rounded, and the Air consists of crystalline primitive rocks, with mica-slate and enormous masses of granite in great diversity of mountain-
forms. From Ghat the general surface of the country continues to rise, and at Selaufet the travellers saw around them the lofty massed walls of their journey of ascent. After the middle of August they experienced the influence of the Soodan rains; the atmosphere then beginning to be humid, and the evenings or mornings being accompanied by fogs. Frequent thunder-storms and heavy rains also occurred at the commencement of the season, when the waters became completely changed, luxuriant plantations of palms being everywhere met with to the south of Taghajit. According to the natives the rainy season lasts till the end of September. At Taghajit, near the frontier of the Upper Benue, Dr. Barth made an excursion difficult and dangerous journey across the Great Desert, believed themselves to be in perfect safety from the attacks of considerable numbers of furious Tuaregics, who had for some time been scattered over the district to murder and plunder them. Between Taghajit and Selaufet, however, at a place about 60 geographical miles farther to the south, on the 25th of August, they were attacked the first time by 40, and the second time by 100 armed men, mounted on camels. By their own courage, however, and the bravery of the Kelowis, their companions, their lives were saved at the expense of a high ransom, and they reached Tintellust, situated 1854, north of the Ungratua, forms. The country around life entirely on the productions of Soodan, in exchange for which they supply Soodan with salt. Every year the Prince Annoor takes the south from 2000 to 3000 camels laden with salt, and returns with slaves and provisions. While the expedition remained at Tintellust, Dr. Barth made a successful journey to Agades, the capital of the kingdom of Air or Asben, which occupied him from the 4th to the 30th of October. Agades, S. 2.] On the 12th of December, 1851, he left Air on their route to Lake Tchad, and arrived at Damergu by the end of December. Here the travellers separated, Mr. Richardson going by the most direct route to Kuka, Dr. Barth southward to Kano, and Dr. Overweg south-west to Maradi and Guber, two states of independent Pagans, where the latter explorer was very kindly received, and obtained much curious information. Kuka, the capital of Bornou, had been fixed as the rendezvous of the travellers, and Drs. Barth and Overweg safely met there again in April, 1851, but Mr. Richardson arrived at the capital to Kano, Kuka a distance of 100 geographical miles W.N.W. from that place, on the 4th of March. The political objects of the expedition deeming now to be the two scientific travellers, Dr. Barth, with Mr. Richardson, was appointed to the south-west of the same as one of the surviving Christians who had come from England to bring presents from her British Majesty. Dr. Overweg also soon arrived. The two travellers were kindly received by the sheikhs and their viziers, and were assisted in all their objects and wishes. Preparations were forthwith made for exploratory tours; and while Dr. Barth was absent on his journey to Adamana, Dr. Overweg put the boat together, and launched it on Lake Tchad. Dr. Overweg embarked, and explored the lake, visiting the Biddunus, who inhabit the islands of which there are about 100 large ones scattered over the lake. On the 29th of May, 1851, Dr. Barth started on his adventurous journey to Adamana, and on the 18th of June reached the great river Benue, which is the native name of the river called on the Tchadda at the confluence of another large river called the Faro. This point of the Benue is about 55 miles higher up than the point reached by Dr. Birket in his voyage in 1854, previously noticed. The Benue is a large river, the average width of its bed running in a general direction from east to west, at the rate of about 32 miles an hour. It is about 800 feet above the level of the sea. The banks are from 20 to 30 feet high. The Benue is separated from the Boko river by a distance of 3 feet deep at the northern part of the Benue. There is a great flood of the Benue inundates the country on both sides. Dr. Barth crossed both the rivers, and proceeded in a south-west direction about forty miles to the town of Yola, which is the capital of Adamana. It is situated in 9° 25' N. lat., 12° 10' E. long., and is a large open place, consisting mostly of conical huts surrounded by spacious courtyards. It is about three miles long from east to west, but does not contain much more than 1000 inhabitants, who are, however, built, and thrash. The town has no industry, and the market is small. The province of Adamana, of which the proper native name is Fumbas, is very fertile, well cultivated, and full of villages. Dr. Barth reached Kuka, on his return, on the 6th of July. On the 11th of September, Dr. Barth set out on an expedition to Kasse, a district on the eastern side of Lake Tchad. On the 18th of September Dr. Overweg joined Dr. Barth on an escort of armed men. They reached Kuka on their return October 14, after having been exposed to much danger from hostile natives. On this expedition Dr. Barth had a favourable opportunity of investigating Lake Tchad. It is a vast lagoon without any means of escape. The current of the river, when moderately full, is about 400 miles, travelling distance, or twenty days journey of about twenty miles a day. It receives only one perennial river, the Shary, which is very large, and in the wet season pours in a large quantity of water. The Shary comes from the south, and enters Lake Tchad at the south end. Another considerable river, the Yeot, or Yow, comes from the west, and enters the lake on the west. The Yow ceases to flow in the dry season. Many of the islands in the lake are permanently inhabited. The swampy parts, in the midst of which numbers of crocodiles and hippopotami, and elephants are very numerous in the vicinity of the eastern side of the lake. On one occasion Dr. Barth saw a herd of elephants proceed- ing along the lake from a distance of five miles, which amounted to ninety-five, and they were walking in a long line, like a regiment of soldiers, the males being in the front, the young ones in the centre, and the females in the rear. On the 25th of November, 1851, Dr. Barth again left Kuka, in order to join a wandering expedition, as far as the town called Mandara. The expedition started on the 6th of December, and on the 30th reached the village of Demmo, when Dr. Barth saw a broad watercourse flowing slowly from east to N.E., shallower than deep enough for canoes, and more than 400 yards in width. The watercourse appears to join the Serbewel, or upper course of the river of Logon, which is the chief affluent of the river Shary. At Demmo a considerable number of females and children were captured. The whole village was destroyed by fire, and made desolate. Slaughtered men, with their limbs severed from their bodies were seen lying about in all directions. The greater part of the men however escaped across the river. There was some fighting, and a few of the Borno army were slain. The expedition continued to the town of Logon. On the 4th of March, 1853, Dr. Barth set out on an expedition to the kingdom of Bagirmi. On the 13th of March he arrived at Logon Birui, capital of the territory of Logon. On the 12th of April he reached the town of Bagirmi, which is situated on the great Benue, and has 400 yards wide. The population of Logon Birui is about 15,000. On the 18th of March he reached the river Shary, 600 yards wide, and was passed over in a large canoe. On the 27th of April he arrived at Massena, the capital of Bagirmi, in 11° 38' N. lat., 16° E. long., and was not allowed to leave the place till the 10th of August. The town of Massena was formerly much larger, and the extent of the wall has been reduced, but is still much too large for the town; and in the utmost state of decay. The town extends over a circumference of about seven miles; but only about half of this area is inhabited, the principal quarter being in the centre, and on the north and west sides of the palace of the Sultan. A deep trough-like depression intersects the town from east to west, which, during the rainy season is filled with water, and in the dry season covered with the richest verdure. The surface within the wall is broken into many other hollows, which contain the wells. On the 6th of July Dr. Barth received dispatches from the Foreign Office of the British government, which were forwarded to him from Kuka, and which authorised him to carry out the objects of the expedition, and supplied him with the means. Lord Palmerston, in his despatch, allowed Dr. Barth the sum of £3000. Dr. Barth determined either to proceed to the eastern coast of Africa, or westwards to Timbuctu. He decided on making the journey to Timbuctu.
The rains had then commenced, and the river was above 1000 yards wide, very deep, and flowing at a rate of about three miles an hour. He crossed the Logusi river on the 14th of August, and arrived at Kuka on the 1st.

On the 20th of September, Mr. Overweg died of an attack of fever. This date closes the 3rd volume of Dr. Barth's Travels and Discoveries in North and Central Africa, 3rd vol. 1853, published by Longmans, Green, & Co., below Shillingford in the 3rd series, 8th vol. on the 28th of November, 1852, and the other volumes, which are to comprise his travels to Timbucto, to resuscitate there, journey back to Kuka, where he arrived December 11, 1854, and his return to England, have not yet (Jan. 1858) been published.

In February, 1853, Dr. Edward Vogel, a young German, employed at Mr. Bishop's Observatory, Regent's Park, Lon- don, was sent to join Drs. Barth and Overweg. He was accompanied by two volunteers from the 3rd series of journeys and missions. They reached Lake Tchad on the 6th of January, 1854, and were received kindly by the sheikh and his wife. Dr. Barth was then absent on his journey to Timbucto. Dr. Vogel is stated to have been put to death by the Sultan of Waday, and his papers have not yet been recovered, nor his fate ascertained with certainty. One of the Sappers and Miners has returned to England; the other, General Maguire, appears to have been assassinated in the course.

Dr. Vogel had sent to England a few notes of his experiences in the course of April, 1856, had crossed the Tchadda at the place where Dr. Balikie had been, in the Pleiad steamer, in 1854.

In January, 1853, accounts were received by the Royal Geographical Society, London, confirming in April, of the successful issue of a commercial journey across the continent of Africa by a Moorish caravan, leaving for ivory and slaves. It had started from Zanzibar on the east coast (9° 6' lat., 20° 9' long.), and had reached a great lake on the west coast, (10° 16' E. long.). The journey occupied six months; a day and a night were occupied in crossing the great lake of Tanganua, also called Passi, Sena, and Maravi. In one part of the journey no inhabitant was seen. The river was well watered.

We now proceed to give an account of Dr. Livingstone's long and hazardous journeys from the interior to the west and east coasts of Africa, the greater part of which were through countries never before seen by any European.

In April, 1852, Dr. Livingstone proceeded to Cape Town, with his wife and children, and sent them home to England. He then returned in order to explore the country in search of a healthy district, which might prove a centre of civilisation, and open up the interior by a path to either the east or west coast of Africa. He was reached Kukan, on his return, by a letter from the chief Sechele that the natives had been attacked at Kolobeng by the Boers of the Cashan Mountains; that the village of Kolobeng had been burned, their goods stolen, and many women and children of the school children carried off for slaves, and his own residence plundered of everything.

Having returned to Kolobeng, and remained a few days with the wretched Bakwains, he proceeded northwards on the 16th of January, 1853. The Bamangwo Hills, between Kolobeng and Lake Ngami, are part of a range called Bakas, which rises about 700 or 800 feet above the plains, and is composed of great masses of black basalt. Its mass of basalt, about six miles long, has tilted up the rocks both on the north and south sides, or about 20 miles beyond the Bamangwo, they found a fine supply of water. This spot was Mr. Gordon Cumming's latest station north. Farther on they came to the hill now 30° 23' S. lat., 24° 13' 60" E. long. It is 300 to 400 feet high, and was the only hill they had seen since leaving the Bamangwo Hills. As they approached Liyani, they found the river-beds filled by the annual inundation, and flowing into the Chobe, which is itself an affluent of the Linyanti. On the 9th of February, 1853, the chief of the Mulolo, named Sekeleti, a young man 25 years of age, married a slave girl named Liyani, numbering 7000 or 9000, received Dr. Livingstone, when they were expecting, with enthusiastic welcome.

The Makolos are the most northerly of the Bechuanas. Having waited a month at Liyani, Dr. Livingstone, attended by a party of the natives, set out from Shebeke,

for the purpose of ascending the Linyanti. Shesheke is about 100 miles east from Linyanti. Linyanti is on the northern bank of the Chobe. The country between the two places is perfectly open, except patchings which are only a foot above the general level. From Shesheke Dr. Livingstone crossed the river Linyanti to Narelie or Nalliele, the capital of the Barotse country, situated in 15° 24' 17" S. lat., 23° 5' 64" E. long. The general course of the Linyanti from the Victoria Falls to Linyanti is 11° 30'; it has procured a sufficient number of canoes, they began to ascend the Linyanti. They had 33 canoes, and about 160 men, Sekeleti and a large party of natives going with them to Narelie. The river, never before seen by European, is magnificent, often more than a mile wide, and with the rapid from three to five miles in length. The banks and islands are richly wooded.

From the bend up to the north, called Katima-Molelo ("I quenched fire"), the bed of the river is rock and sandstone, runs fast, forming a succession of rapids and cataracts, which prevent continuous navigation when the river is low. The rapids are not visible when the river is full, but the cataracts of Namblo, Bomhwe, and Kale, must always be dangerous. The fall at each of these is between four and six feet. But the falls of Gonye present a much more serious obstacle. There they were obliged to take the canoes out of the water, and carry them more than a mile by land. The fall is about thirty feet. The main body of water, which comes over the rocks of rock at the fall, is collected into a space of 70 or 80 yards before it takes the leap, and a mass of rock being thrust forward against the roaring torrent, a loud sound is produced.

The rocks here are those of a red, hard, weathered, sandstone, with madrepore holes in it. This and broad horizontal strata of trap, sometimes 100 miles in extent, and each layer having an inch or so of black silicious matter on it, as if it had flowed there while in a state of fusion, form a great part of the bed of the central valley of the Nile, and the southern part of the country especially, are often covered with 12 or 16 feet of soft calcareous tufa. The banks of the river in this part, viewed from the flat rockly basin in which it flows, presented a feature which it is difficult to portray, 300 or 400 feet high, and stretched away to the N.E. and N.W. until they were 20 or 30 miles apart. The intervening space, nearly 100 miles in length, with the Linyanti winding gently near the middle, is the true Barotse valley. It bears a close resemblance to the western valley of the Nile, and is inundated annually, not by rains, but by the Linyanti, exactly as Lower Egypt is flooded by the Nile.

The villages of the Barotse are built on monads, and during the inundation the whole valley assumes the appearance of a large lake, with grassy monads on which migratory flocks of birds occur in Egypt with the villages of the Egyptians. The Barotse are strongly attached to this fertile valley. They say, "Here hunger is not known." There are no large towns, but here and there are mound buildings, and the mounds being made of mounds of sand artificially constructed. When the river is compressed between the high rocky banks near Gonye, it rises 60 feet. The river presented the same appearance of low banks without trees as it assumed when they came to 16° S. lat. until they arrived at Liboana, 14° 28' S. lat. Twenty miles beyond that there was forest down to the water's edge, and then there were teak. No locality can be inhabited by Europeans where that scourge exists.

Finding that he was near the confines of his territory, the river of Londa or Locti, and having passed it, Dr. Livingstone, and the chiefs of that country being reported to be friendly to strangers, Dr. Livingstone pushed on to latitude 14° 11' 3" S. There the Linyanti assumes the name of Kalombo, and seems to be coming from the east. It is a fine large river, about 200 yards wide. The Lelua is about 250 yards wide, and comes from the N.N.W. The Locti, about 200 yards wide, enters here from the W.N.W. The waters of the Locti are of a light colour, and those of the Lelua a dark mossy hue. The Locti enters the Lelua in a little lowering. The numbers of large game above Liboana are prodigious, and they are remarkably tame: 31 buffaloes defied in slow procession before their fire one evening, within gun-shot; and herds of antelopes and hartebeests, 2000 yards distance. The lions were in great numbers, as is always the case in Africa where game abounds. A party of Arabs from Zanzibar were in the vicinity at this time. After remaining some days in this country, Dr. Livingstone returned to Linyanti, and made preparations for his journey of
to Loanda, on the west coast of Africa, as soon as the cooling influence of the rains should be felt in November.

He had few scientific instruments, but they were of the best kind—a sextant by Troughton, a chronometer by Dent, a thermometer by Doll, a compass from the Cape Observatory, and a small telescope.

On the 11th of November, 1833, he left the town of Linyanti, accompanied by Sekelute and his principal men, to embark on the Chobe. They crossed five branches. When on the banks of the river they took up their deep race small boats. The banks are of soft calcareous tufs, like those of the Zongas. The bed is deep, and the sides perpendicular. The course is extremely tortuous.

The distance of the Chobe from the Leebame is undefined, on account of each dividing into several branches before they unite, but when the whole body of water collects into one bed, it is very wide, and is a goodly sight for one who has spent many years in the thirty south. Turning round they began to ascend the Leebame, and on the 19th of November reached the village of Shesheke. After a short stay they proceeded up the Leebame. Their progress was slow, owing to their waiting at the different villages for food.

This journey to the west coast, was accompanied by a band of 27 men, belonging to the Makololo. It was the dry season. Parts of the river were only about 200 yards wide, and very deep. In other parts it is spread out to more than a mile, and the water flows rapidly over the beds of rock which require great care to manage the canoes in these shallow parts. The rapids are caused by rocks of dark-brown trap, or of sandstone stretching across the stream. In some places they form miles of the rocky bottom, with illets covered with trees. Leembate is the last town of the Makololo, and is situated on a mound like the rest of the villages in the Barotse valley.

On the 27th of December, 1833, they were at the confluence of the Leebame and Leebame, 14° 10' 52" S. lat., 23° 20' 10" E. long. From the confluence down to 27° south there are many long reaches where a vessel equal to the Thames steamers plying between the bridges could run as freely as they do on the Thames. It is often, even here, as broad as that river at London Bridge, and perhaps as deep. They have also wood and some birds of passage to a continued navigation for hundreds of miles at a stretch. About ten miles below the confluence of the Loeti, for instance, there are many large sand-banks in the stream; then there are a hundred miles to the river at Simath, where a Thames steamer could ply at all times of the year; but again, the space between Simath and Katima-Molelo has five or six rapids, with cataracts, one of which, Gonye, could not be passed at any time without portage. Between these rapids the river is narrow and deep, and the descent of several miles is at once a vertical fall. Beyond Katima-Molelo to the confluence of the Chobe there are nearly 100 miles again of a river capable of being navigated in the same way as in the Barotse valley.

The river rides down the Leebame. The water is dark in colour as compared with the Leebame, which here assumes the name of Kabombo. The Leebame flows placidly, and, unlike the main river, receives numbers of little rivulets from both sides. It winds slowly through the most luxuriant meadows, each of which has a soft sedgy centre, or a large pond, or else a gentle riff flowing down the middle. The meadows are probably inundated, as the trees are on spots elevated three or four feet above the meadows. The rains were now set in, and the travellers were much drenched.

When they had descended something more than one-third of the Leebame, they left the river, and travelled overland on the eastern side by the village of the chief Shinte, till they came to the Lake Dilolo. On their route they crossed several affluents of the Leebame, and travelled over extensive plains, much of which was under water.

On the 20th of February, 1834, they reached the small end of the Lake Dilolo. Dr. Livingstone, being exhausted by fever and abstinence, could not visit the wider end. After passing a branch of the N.W. coast of the lake, which flowed northwards into the fine river Kasai, or Lokë, which has a northern course, while all the rivers they had previously passed flowed south wards; thus showing that the flow is parallel in which the Lake Dilolo stands an elevated flat which forms the confluence of the streams that flow to the north and south respectively.

On the 4th of April they reached the banks of the Quango (Coango), a river 160 yards wide, and very deep. This fine river flows among extensive meadows clothed with gigantic grass and reeds, in a direction nearly north. They crossed it after a dangerous contention with the natives, and passed on westwards to the village of Cassange (pronounced Cais- cange), which is the farthest station eastward of the Portuguese. They were now safe, and in the kingdom of Angola. Cassange is situated in 9° 37' 30" S. lat., 17° 49' E. long. The distance to Loanda is about 300 miles. On the 14th of May they reached the village of Quango Alto and Cassange on the N.E. coast of Angola, or rather May, arrived at Loanda. St. Paul de Loanda has been a very considerable city, but is now in a state of decay. It contains about 12,000 inhabitants, most of whom are people of colour. It possesses two colleges, one of which, formerly a Jesuits' college, is now a workshop. The forts are in a good state of repair. The Portuguese bishop of Angola resides at Loanda, and was very kind to Dr. Livingstone. The harbour is formed by a low sandy island, between which and the mainland is the station for ships. There was not a single English merchant there, and only two American merchants. Mr. Gabriel, the British commissioner for the suppression of the slave-trade, treated Dr. Livingstone with great kindness and hospitality.

On the 20th of September, 1844, Dr. Livingstone and his party were on the coast, separated from their servant by the river Quango, and on the next day proceeded into the territory of Linyanti. They passed round to the mouth of the river Bengo, and ascending that river, arrived at Icollo Bengo, and on the 28th of September at Kalamungwo, on the same path by which they came. The Bengo is also cultivated. Dr. Livingstone proceeded in a canoe down the river Lucalla to Massangano. The river is about 85 yards wide, and navigable for canoes from its confluence with the Coanza to about six miles above the mouth of the Bengo. It is situated in the midst of a group of curious columnar-shaped rocks, each of which is upwards of 300 feet in height. They are composed of conglomerate in a matrix of dark red sandstone, and rest on a thick stratum of this sandstone, with very few of the peculiar figures of the Coanza. The extent of the Coanza reach is reported to be thirty leagues below Pungo Adongo.

On the 1st of January, 1845, they departed from Pungo Adongo. Their path lay along the right bank of the Cassange. On reaching the confluence of the Lembe, Dr. Livingstone left the river, and proceeded in a north-easterly direction. Passing over the heights of Tala Mengongo, 9° 45' 37" S. lat., 17° 27' E. long. (Jan. 15), they arrived again at Cassange.

On the 28th of January they crossed the Quango in canoes. Having reached the eastern side of the river, they ascended the eastern activity which bounds the Cassange valley, and found it to be 6000 feet above the level of the sea, the bottom of the valley being 3500 feet. They crossed the Lombe, which is more than one-third of the height of London on the west. On the 25th of March they crossed the Chikapa, and then the Kamane, an affluent of the Chikapa, coming from the S.S.W. On the 30th of April they reached the Bongonde, where they had to ford a ridge to cross.

On the 7th of May they arrived at the Moseango, a stream 30 yards wide, which they crossed by canoes, and arrived at Cabango, a village on the banks of the Chilombo, in 9° 31' S. lat., 20° 31' E. long.

On the 18th of May they came to the main village of Bango, and on the 28th reached the village of the chief Bango, 12° 29' 53" S. lat., 20° 58' E. long. On the 30th of May they left the village of Bango, and proceeded to the river Loembwe, which flows to the N.N.E., 50 yards wide, and 4 feet deep. Hence they reached the village of Kawama, who wished to detain them, but being one of his hidden canoes by night, they crossed to the southern bank of the river Kasai.
After leaving the Kasai they entered upon the extensive level plains which they had formerly found flooded. On the 12th of June they found the Lotembwa, there about a mile wide and very deep, and regained their former path. It is a N.W. of Lake Dilolo, and seems to flow from it northwards, and enter the Kasai, whilst another river Lotembwa flows from the other end of the lake southwards. Thus, this little Lake Dilolo, by giving a portion of its contents to the Kasai, the latter is that of its tributary its waters to the Atlantic and Indian Oceans. From these elevated plains all the rivers seem to unite in two main drains, the one flowing to the north, and the other to the south. The northern drain, the Kasai, flows eastwards and joins the southern by the Zambesi to the east. Dr. Livingstone was thus on the watershed, or highest part, of those two great river-systems, but still not more than 4000 feet above the level of the sea, and 1000 feet lower than the top of the southern ridge they had already crossed. Instead of lofty snow-clad mountains appearing to verify the conjectures of the speculative, there were extensive plains, over which a person may travel a month without seeing anything higher than an ant-hill or a tree.

Sir Roderick Murchison, in his Address, as President, to the Royal Geographical Society, in 1852, explains the peculiar geological structure of the African continent. "Such as South Africa is now, such have been her main features during countless ages, and have been modified by the movement of the great continents. For the old rocks which form her outer fringes unnotionably circled round an interior marshy or lacustrine country, in which the dicyonod flourished, at a time when not a single animal was similar to any living thing which now subsists, and then progressive, the central and meridian zone of waters, whether lakes or marshes, extending from Lake Chad to Lake Ngami, with hippopotami on their banks, are therefore the great modern residual geographical phenomena of those of a mammalian age. The differences, however, between the geographical past of Africa, and her present state are enormous. Since that primeval time the lands have been much elevated above the sea-level, 

Dr. Livingstone having resolved to make a journey to the east coast of Africa, two routes offered themselves, one in a direction N.E. by the town of Cazembe and the southern end of the Lake Tanganyika to Zanzibar; the other nearly east by the course of the Zambesi. He chose the latter. On the 31st of December, 1855, he left Linyanti early in the morning. Dr. Livingstone having resolved to take a journey to the east coast of Africa, two routes offered themselves, one in a direction N.E. by the town of Cazembe and the southern end of the Lake Tanganyika to Zanzibar; the other nearly east by the course of the Zambesi. He chose the latter.
passed their route numerous villages inhabited by the Batoka. On the 18th of December they reached the bank of the Kafue, a river upwards of 200 yards wide, and full of islands. From there on the 25th, they arrived at the Zambesi, in order to form an establishment in a healthy locality, and to enter into friendly commercial relations with the natives. He will be supported by the British government, and his project has received the sanction of the King of Portugal. A middle passage has been provided, and he will be accompanied by three or four scientific gentlemen, who will assist him in his well-intentioned labours.

In 1854, Lieutenant Burton of the army of the East India Company, on a hazardous journey to Mecca and Medina, performed a short but still more perilous journey to Harar in the Somali peninsula, of which he has given an account in his 'First Footsteps in Eastern Africa.' Though at no great distance from the town, he finds its elevation of 2500 feet, and the sea gives to this country a comparatively temperate climate. Fortified sufficiently to repel the incursions of the surrounding savage tribes, and under the rule of a young and very arbitrary sultan, Harar enjoys the eminence of a considerable traffic in choice produce, more particularly coffee. [HARAH, S. 2.] Lieutenant Burton has since undertaken a journey from the eastern coast of Africa in the direction of the Lake Nyasi, yet unvisited by Europeans, and may possibly reach it in 1858; but the question which has excited the curiosity of the learned world from the time of Herodotus to the present day.

AGADES, or, as the Turcics call it, £kade, is a town of Africa, situated in 19° 23' N. lat., 7° 30' E. long., on a large river called the Zambesi, the capital of the kingdom of Air or Asban, with which we have recently become acquainted through the travels of Dr. Barth, who visited Agades in 1850. No author is known who has mentioned this place before Leo Africanus, in whose time it was a flourishing town. Agades from its situation, must always have formed an important central place between the Kelowas and the tribes inhabiting the districts to the south and west. There are traditions among the inhabitants of the period of the Greek occupation of its originating from the north, probably belonging to the Berber race. There is, no doubt, a good deal of slave blood among the present inhabitants of Agades, as is the case with the whole population of the south-eastern portion of Air; but there must have been a very ancient stock of indigenous black people, who have transmitted a peculiar language of their own, which is the same language as that spoken by the people of Timbucto.

Agades is now contained not less than from 50,000 to 60,000 inhabitants. Dr. Barth was assured by the Turcics, one of whom had been at Timbucto seven times, that it was much larger than that place. At present the appearance of the town is that of an almost ruined place, scarcely the sixth part of the houses remain, and about 700 houses only. The number of the inhabitants is estimated to be from 7000 to 8000, who are partly merchants and partly artisans. The merchants seem to visit only the markets of Katsena, Tasawa, Marado, Kano, and Saccota, and do not go to the northern markets of Ghat or Murunk, unless on a journey to Mecca. There exists no intercourse with Timbucto. The commerce of Agades itself is principally in millet, which constitutes the principal food of the inhabitants. The manufactures are very limited, consisting mostly in cloth-work and mats. The saddles made in Agades, particularly those used in riding upon the mohers, or swift camels, and also the sandals, are far famed.

Sailing down the branch of the river on which Kiliman stands, they reached that village, it being then May 20, 1856, only a few days less than four years since Dr. Livingstone started from the Cape. Kiliman is in 17° 55' 8' S. lat., 36° 40' E. long. The village stands on a great mud-bank, and is surrounded by extensive swamps and rice-grounds. Dr. Livingstone waited there about six weeks, when he Majesty's brig 'Agnes' arrived, and went, and there is a dangerous bar at the mouth of the Kiliman branch.

Dr. Livingstone left Kiliman, July 12, 1856, and arrived at Mauritius, August 12. He returned by the Red Sea and the Overland route, and arrived in England on the 12th December, 1856.

The preceding sketch of Dr. Livingstone's arduous journeys is taken from his interesting volume, 'Missionary Travels and Researches in South Africa, including a Sketch of Six Years' Residence in the Interior of Africa, and a Journey from the Cape of Good Hope to Loanda on the west coast; thence across the continent down the river Zambesi to the Eastern Ocean,' Svo. 1857.
AGD

water near the town, and there is also plenty of brushwood.

AGDE. [HEBRUART.] AGNES. [SOMERSET.] AGNER. [CORNWALL.]

AGRICULTURAL IMPLEMENTS. Few of the pro-
ductive arts have made more rapid progress within the last
few years than those relating to the cultivation of the soil.
In the application of chemical terms and in the develop-
ment of practical science to implement-making, this advance has
been equally observable. When the corn-

laws were repealed, and agriculturists were deprived of the
support—or, perhaps it would be more correct to say,
refused of the protection—without which the progress of
energy was thrown into those two departments of industry.
As a consequence, greater improvements have been developed
in twelve years, than in twice or thrice that space of time
under the old order of things.

When the jurors prepared their report on the Agricul-
tural Implements displayed at the Great Exhibition in
Hyde Park in 1851, they grouped them all under certain
headings, according to the kind of service they were intended
to render in field and farm; such as Instrument of
Tillage—Implements used in the Cultivation of Crops;
Harvesting Implements; Preparations for Market; Machines
for Preparing the Food of Stock; and Draining. Such
will also be a convenient mode of grouping to adopt here.

Instruments of Tillage.

Ploughs.—Until about the year 1840, four-horse ploughs
were still used in many parts of England; notwithstanding
that in the very same parishes ploughs with two horses
had been tried for a considerable time. The second
plough had been adopted for clay soils, when such formed
the chief corn-lands throughout the island; but they
were not suitable for an altered state of agriculture, when
the rotation of crops was adopted and the grass
became corn-lands. Even when the swing-plough was
invented as an improvement on the old wheel and gallow
plough, the weight of draught was little less than before.
It was the Messrs. Ransome of Iewish who furnished the
modern improvement and introduced forms of mould-
boards adapted to different soils. Messrs. Howard and Mr.
Busby afterwards paid particular attention to the curvatures
of the mould-board; for this is indeed the essential act-
ing part of a plough; raising, turning-out, and throwing over
every furrow-well of earth in true parallelism with other
slices. Foreign agriculturists have often expressed
surprise at the length of the mould-boards in modern
English ploughs; since it is seen that short boards are
better adapted to raise the soil while they turn it over; it
has been found, however, by experience, that clay lands
require longer mould-boards than those which are drier
and lighter; and hence a plough suitable in England might not
be so advantageous in Scotland, or on the continent.
Among the various varieties of ploughs exhibited at the
trial at Mr. Pusey's estate in Wilthorpe, by Mr. Miles,
Mr. Shelley, and Mr. Owwithead; while eleven others were tried
at Mr. Mech's farm in Essex, by Baron Mortens D'Osten,
Colonel Challoner, and Mr. Johnson. Of the former group,
six were two-wheel, three one-wheel, and six swing-
ploughs. Some were found best at a seven-inch furrow;
some broke the land too much in a furrow of that depth.
All the swing-ploughs were clearly ascertained to be inferior
to those with two wheels. It was further found that a
particular curvature of mould-board suitable for a five-inch
furrow worked unsatisfactorily in one of seven inches—
showing, as many an old farmer would be astonished to hear,
that there are mathematics even in farming. The Royal
Agricul-
tural Society had in recent years recommended the use of
ploughs for two distinct purposes—the ordinary plough,
and a deeper ploughing once in four years, when the
root-
crop recur, to give the land more thorough stirring. A
common plough is fitted with a sickle scythe, but Mr. Meall
and other makers have constructed powerful ploughs, to
be worked at leisure in winter with four or six horses.
Mr. Fisher Hobbs, in reporting on the ploughs exhibited at
Culthie Agricultural Show in 1850, said that enough had been
invented to plant the land, and dig another, but it was
now introduced in recent years, in nearly all parts of the
English plough. Eleven ploughs were tried on a strong loamy soil, with
a considerable quantity of herbage upon it. The Cumberland
swingle-ploughs were found decidedly inferior in power and
efficiency to ploughs with iron wheels, made by Ransome,
Howard, and other celebrated manufacturers; these latter,
averaging about 90s. in price, were pronounced to be among
the best ever produced. A machine for deep ploughing, by
Methus. Ransome, was two feet deep, and whose plough
and as well laid as any produced at shallower depths.
Some persons have expressed an opinion that the plough has
now reached the highest point of perfection; but Mr. Fisher Hobbs
remarked with praiseworthy caution, "I still look forward to
the day when the plough will be adapted to the present operations on
the soil, and for leaving the land in a fit state for drills or other machines required
to complete its cultivation.

Harrows.—The harrow was always made with square
bars and square-set teeth; but as it was difficult to make
such a harrow work equally in different tracks, even though
dragged from the corners, modern makers have constructed
harrow which have the teeth set cross-wise, enabling the
harrow themselves to be-chime against each other's
expanding harrow is a very complete implement. The
bars at every point of crossing are united by a loose pin,
on which they work freely; the width of the harrow can
thereby be increased or diminished; the tines, according to
the state of the land, can be brought nearer together or
spread wider apart; and there are small wheels, easily let
down, by which the harrow can readily be moved from one
field to another, without disturbing its general mechanism.

Rollers.—The late Mr. Pusey, one of the most enlightened encouragers of scientific
agriculture, "the landlord was often asked by his tenant for
some old tree to convert into a roller; the tree roller, when
manufactured, had its framework loaded with rough mate-
els, but it soon turned black and could never become
in a year a most unignis instrument." Iron rollers of excellent construction have since been introduced.
Their regularity of surface has, however one disadvantage, in
pressing over small cloaks so smoothly as to make the
soils, and not to grind them. Mr. Class, of Belgium, has invented
a roller, intended for narrow round ridges, but also fitted to
produce the action just adverted to; it consists of four rings or
partial rollers, so adjusted on one axis as to have independ-
ent motions, and to produce a mass of loose particles
the soil have, however, been nearly superseded
by

Clod Crushers.—This apparatus, invented by Crosskill,
is used chiefly for breaking down turnip land which has been fed
off by sheep in wet weather and afterwards backed by the sun;
it is also a good presser for green-maize; and is made
on or to grind them. The架ged iron teeth form the chief
characteristic of this implement. Mr. Gibson has since in-
volved the jointed or crosswise, produced the favourite
rows of very narrow wheels, alternating one with another.
Each of these kinds of clod-crushers has some advantages
over the other. A third variety, of later introduction, is
known as the 'Self-Cleaning Clod-Crusher.' It contains a
series of eccentric wheels upon an axis, which, in revolving, rub
and clean each other.

Scorifiers, Grubbers, and Cultivators.—The implements
denoted by these several names are intended to save a great
part of the time spent in ploughing on the old method.
in an ordinary four-course system of arable culture, the land
receives seven or eight ploughings in the four years; but
if a scorifier is employed to parcel the surface to a depth of two
inches immediately after the wheat harvest, much of the
four years' labour will be economised. From this time
there may be likely to many ploughs set abreast, so as to cut up
and turn over a slice of soil five, six, or seven feet in width. Not
only is the time spent in ploughing lessened, but less sub-
sequent employment of the harrow and the roller is needed.
Many forms of these time-saving implements have been in-
vited. Coleman's scorifier, with six horses, is adapted for
very hard ground. Biddle's, made by Messrs. Ransome,
is suitable for going deeper into looser ground. Kilby's and
Bentall's ploughs, this latter patented in 1846, are used for
ordinary ploughs and scorifiers, and are useful for a very
close surface of land. Cotgreave's plough is a cultivator, in
which these processes are combined in rather a curious way;
it first ploughs and turns a furrow five inches in depth; then
rolls the ground over, and afterwards works the harrow over
it on the top of the first; and lastly, a sub-pulveriser
loosens the soil to a further depth of 3 or 4 inches. Beau-
clerk's patent plough and subsoiler may be likened to a
common plough with an Archimedian screw attached, which
revolves in the bottom of the furrow, thus ploughing and

Digitized by Google
superseding at the same time. Such farmers as have duly provided themselves with some or other of these various instruments, may learn to cultivate seven or eight to two or three in the four years. In 1851 Mr. Pusey said:—"I will venture to add, what may appear theoretical, that if every steam be employed successfully in cultivating the field, why be less by ploughs or digging than with an implement like one of these cultivators; because they are able to work so much wider a space as they pass along in their course." Some of these implements have shares, some points, to dig into and turn up the soil. Several have been made to introduce steam-cultivators. One, exhibited by Mr. Usher in 1855, consists of a steam-engine moving itself by the revolution of a large circular roller placed under it; and to it are attached numerous ordinary plough-shares reversed, revolving behind the engine. Another, also made by Mr. Fitch, consists of two ordinary ploughs fixed to a carriage or framework of iron, and moved by an endless rope communicating with a steam-engine fixed in one corner of the field. Others have since been brought forward; but this department of the art is confessedly in its infancy.

Implements used in the Cultivation of Crops.

Drills.—The drill has almost driven the hand-sower from English farms. One half of the horse-power formerly expended in harrowing is saved by the adoption of some of the modern drills or sowing-machines; a saving of seed is also effected; and there is also an avoidance of the necessity of borrowing into the same ground at a particular angle, which was formerly deemed necessary as a preliminary to hand-sowing. The drill, in fact, is the key to a whole system of husbandry; for, in addition to the advantages just enumerated, the drill is applicable to the use of many artificial manures, many sowing them beneath the ground, special coulters, and covering them with earth, that their excessive strength may not injure the seed, which is deposited last of all; while the use of the horse-hoe is almost wholly dependent on the previous use of the drill. Drills of recent invention exhibit much variety and ingenuity of construction. Some are for general purposes, capable of drilling with or without manure, wheat, beans, and turnips, at the different intervals suited to those seeds respectively, from seven inches up to two feet. Some are turnip drills, in which manure, generally ground bones, or superphosphate, is distributed as well as seed. Some, for use in unusually dry weather, pour down each manure-coultar the requisite amount of water mixed with powdered manure. Some, to economize in the manure, close the seed and the manure only at those spots in the lines or rows where the plants are intended to stand without molestation from the hoe; each machine having a power of adjustment to different widths or different numbers of seed-rows. Some, the wellcelebrated machines of Messrs. Garrett, have contributed to the excellence of the modern drills. Messrs. Garrett have improved the wheeling or moving power of the general-purpose drill, to the ease of the horse and the driver; the turnip drill they have greatly improved; and they have constructed a hand-barrow drill for distributing grass-seed broadcast in a very effective manner. Messrs. Horse-bay have constructed a drill for depositing manure-dust and turnip-seed on ridges, and reducing the ridge by concave rollers to a compact rounded form; they have also introduced India-rubber tubes for conducting the seed down to the channel made by the coultar, instead of using a series of tin cops; and they have also done much to enable the drill to deposit seed and manure on hill-sides, and to work equally well on ridges and on the flat. "The smaller drills have invented a steartage corn-drill," adapted for being driven with great nicety, and for delivering the seed equally well going up or down hill. One of the drills lately invented is especially contrived for distributing equally well liquid manure or the solid manures. In short, the drill is now an implement to which all the makers devote some sedulous attention.

Top-Dressers or Manure-Distributors.—Although wheat is sown by the hand-sower, the manure is usually provided with its requisite nitrogen by farm-yard dung or by sheep-folding, yet it generally requires a top-dressing of manure during its growth. This need to be applied by hand; but several machines, of which one is by Mr. Holmes, have since been invented to perform this service. It distributes three or four bushels per acre of guano or nitrate of soda, or a larger proportion of rape-cake or superphosphate, on wheat in the spring of the year. The machines are much more simple than drills.
by Crosskill; one of M'Cormick's improved by Lord Kinm;
under, another of the same inventor, improved by Burgess
and Key; and one of Hussey's, improved by Messrs. Dray;
and one of it was adopted by Palmer. The prices ranged
from 25L. to 42L. That was the first of them. The other
and again on Mr. Miles's estate at Leigh Com-
in three fields exhibiting striking contrasts. The machines were
worked from morning till night—each in cutting both wheat
and oats, and the cord-cutting, another in threshing, and
there was a constant exhibit of steam powerful enough to
barns by fixed engines, it is perfectly feasible in the open
air by a locomotive engine—a plain, healthier and more
expedient for the laborer, and rendering probable a
considerable saving of farm buildings requiring to be
constructed by the landlord. The Agricultural Society gave
the first impetus to the construction of move-
able steam-engines for farm purposes; and the annual prizes
and exhibitions have been very influential in determining
the interest of the farmers to adopt the improvements. For
example, in the year 1851, there were engines of this kind exhibited, made
by Horseby, Tuxford, Clayton, Barrett, Hensman, Bullin,
Roe, Ransome, Garrett, and other makers. Every one felt
that the invention was still in its infancy; for the worst
specimen exhibited consumed three times more coal than the
best. Of thirteen specimens examined, the nominal horse-
power varied from 4 to 9; the time of getting up steam,
20 to 83 minutes; the coal used in getting up steam,
10 lb. to 75 lb.; the steam used, 6'79 lb. to 25'80 lb. Mr. Locke,
reporting on these trials, said, "If I might be permitted to
suggest a little advice to the makers of these engines, I
would beg of them to attend more to the proportions of
the whole ; for I am quite convinced that the want of
success is a want of good proportion in several of the engines; and
this to a mechanic or an economical farmer, is of more
importance than a profusion of brass."

At the Carlisle Agricultural Meeting in 1855, a manifest
improvement in the expense of the engines can be noticed.
The maximum consumption of coal per horse-power per hour
was 10 lb.; while the minimum (in Messrs. Tuxford's engine)
was only 3'7 lb. It was, however, considered by some of the judges that this element of merit had been somewhat
asked with prejudice, and that a certain competition laid down by the Society for portable engines
have unfortunately led to the production of engines only
intended for winning the Society's prizes, and known as
"racing engines," required the nicest care; instead of these
simple and effective engines which may be safely entrusted
to the management of intelligent farm-servants; " and it
was recommended in future " to submit the prizes engines to
subsequent trials, for a prolonged period, under the
ordinary management of a farm establishment."

At the Salisbury Agricultural Meeting in 1857, there were no fewer
than twenty exhibitors of agricultural steam-engines; of
which one firm, that of Messrs. Clayton & Shuttleworth,
made at the rate of 600 engines per annum. In some of the
engines exhibited, the drivers are two men. However, an intelligent farm-labourer, may be seen driving the barn
machinery, cutting chaff or roots, crushing oats, grinding
corn, polishing mangold-wurzel, splitting beans, sawing wood,
pumping water, and lending its boiler for steaming potatoes
or rice.

**Threshing-Machines.**—Threshing-machines worked by
horses were considered, in their day, a vast improvement
over the flail of earlier times; and so they unquestionably
were. It occurred to Mr. Amos, the agricultural engineer, how-
ever, that a large amount of power was wasted in dragging
dead weight; and he found on experimenting in 1849, much to
the astonishment of farmers, that in a four-horse machine the
strength of three horses was expended in moving the wood
and in the beat of walking, and only one horse was really
available in threshing the corn. The makers immediately began
to reform their methods of construction; and they gradually
succeeded in bringing down the friction and dead weight
to two and a-half, two, one and a-half, and even one horse out
of four. At that point, however, the higher class of farmers
began to think more of steam-threshing than horse-threshing.
In the one case, as in the other, the threshing arms or levers
begin their work as soon as a central axis or shaft is set in
motion; whereas the horse is only begun to work half a minute
after the machine is set in motion. Several threshing-machines were tested by the
Exhibition Jury in 1851; they differed greatly in excellence;
bio not on an average they required fifteen-horse power to
thresh two and a-half cwt. of wheat sheaves per minute, or
nineteen-horse power for barley. The engine and machinery
that those which worked with least horse-power were not
necessarily the best in the quality of work done, as denoted by
the three tests of excellence—clean threshing, unbroken
preparation, and grind.
grain, and uninjured straw. Malsters continued up to that year to distrust machine-threshed malting barley, on the ground that it was often too much bruised and injured for germinating. The makers had therefore every reason to try and improve these threshers. It was calculated that wheat is usually threshed for about 3s. 6d. per quarter, all expenses included; whereas steam threshing cost less than 1s.; and that, therefore, to make the new, the old steam threshing would be unquestionable. By the year 1855 the improvement in the machines was most decided. There were several exhibited in that year at Carlisle, of about eight-horse power, which threshed about 200 sheaves in twenty minutes. The judges, in reporting on the trials, said, "These machines are now become of material importance, inasmuch as they enable the farmer in so short a time to prepare the corn for market. They have, in fact, almost entirely superseded the flail; and without their powerful aid the full supplies of corn could not this autumn have been furnished for consumption. The extraordinary demand for the threshing machine, and its daily use on the farms, are circumstances that prove its estimation by the agricultural community." A fixed steam-engine, working systematical barn-machinery, threshes corn more economically and effectively than portable machines; but the latter are of great importance in so far as they can be let out by their owners to different farmers to be employed according to the exigencies of the harvest. No kind of agricultural machine has met with more opposition from hand-labourers than threshing-machines; but the prejudice in favour of the old and inefficient way is dying out in this as in other directions. It is said that in 1845 a muster of 1000 was held at Salisbury in 1830 for firing barns containing machinery; whereas in the same town in 1857 the labourers cheered loudly on witnessing the success of the reaping machine.1

Winnowing-Machines.—Instead of threshing the threshed corn to the wind, as in the old process, it is now winnowed by very ingenious and intricate machinery. Messrs. Hornsby were among the first to achieve success in the construction of such machines. Their winnowing apparatus is fitted with a spike to receive corn by a gently converging sort of hopper; it separates the corn from the chaff in the rough pulpy state, as it comes from the threshing machine, without being previously riddled; and it can be adjusted to suit corn either in rough chaff or in any other state. The meshes of the grating are so varied, and placed in such relative positions, that the winnowing-machine will separate the whole produce of the threshing-machine into 'best corn,' 'good tallings,' 'tallings,' 'whites,' 'screenings,' and 'chaff,' at the rate of fifty bushels and directed to the chaff, at the rate of twenty quarts per hour. Not only has the flail been nearly superseded by the threshing machine, and horse-power by steam-power, but the threshing-machine itself, instead of being a mere box for beating out the corn in a rough way, has of late years been improved and adapted in order to combine the threshing and winnowing machines in one, beating the grain from the ears, and then cleaning and separating it ready for market.

Machines for Preparing the Food of Stock.

Turnip-Cutters.—Formerly farming stock was fed with hay, or turned out to pick over straw, occasionally mixed with turnips; but scientific and practical men aided each other by degrees in discovering that this labour of the jaws wasted the muscle of the animals, and retarded their progress. Hence the invention of many ingenious machines for facilitating the preparation of food for live stock. One of these is the turnip-cutter or cutter, in which small pieces one important variety of this food. Some farmers have asserted that lambs fed with machine-cut turnips are at the end of a winter worth 5s. per head more than other lambs which have wasted their muscle in masticating whole turnips; and assuming this to be true, it has been calculated that, allowing for wear and tear and labour in using the machine, the improvement is equivalent to a saving of 70s. per acre upon turnip crops. These estimates are frequently disputed in detail; but there is no doubt that the saving is a real one, and that its amount may be at least 50s. per acre. The act by sharp-edged instruments, working horizontally or vertically according to the nature of the machine adopted. Some of them cut turnips for cattle-food; some for sheep, according to the nature of the machine.

Chaff-Cutters.—The cutting of straw into very small pieces, to supply the deficiency in natural chaff for cattle-food, was at first done by hand, with a sort of knife hinged at one end; then by a series of knives working round an axis, the old pieces of straw being shaken off; then by a fixed or movable steam-engine on a farm. The process now costs only one-sixth or one-eighth of the charge formerly incurred. The machine is useful even to cut hay itself as a means of facilitating the masticatory process. In this machine, if necessary, the 'hopper' is in, by which the straw is conveyed to the machine, thence by a conveyer to the hopper, and it is then cut by the machine, and the cutting machine is separated therein. Corns cut 14S. lbs. of chaff per hour, by steam-power, those that worked by the muscular power of one man each cut quantities varying from 90 to 310 lbs. per hour.

Coma.—By the year 1855, a large number of modern improvements, both by the crushing movement of rollers rather than the grinding movement of mills, and are intended to facilitate the commination of substances for cattle-food. One is a lined seed-crusher; another a corn-crusher; the third an oil-cake bruising mill; the fourth a fine-mash mill; a fifth a coarse bruise. It is evident, from a mere inspection of this list, that there is much scope for ingenuity in the arrangement of working parts for such machines. Some of the fine-mash mills, made principally for barley, beans, and oats, admit of adjustment which will enable them to grind anything from lined up to flint-stones." Messrs. Hornsby, Garrett, Crosskill, and other manufacturers, now make steam-worked oil-cake breakers that will break 3000 lbs. of oil-cake and make fine meal at one operation.

Pulping-Machines.—Farmers are not agreed concerning the amount of advantage derivable from the reduction of root-food to a softened state. In reference to potatoes, it has been found worth while to steam potatoes for pig food; and in another case, and for the use of cattle, such as turnips, which, being thus treated, may be rendered good victuals to be stored up for months. The pulping of turnips enables the root to be incorporated with other nutritious articles of food; but on the other hand, there is a tendency to cause a partial or total, or sufficiency, of the liquid from the solid portion, and then much of the saccharine qualities is lost in the liquid. The turnip pulping machines, which are both hand-worked and steam-worked, are on this account less decidedly successful than most modern agricultural implements.

Draining.

Tile-Machines.—There is much land that does not require more draining than the farmer can easily effect in the course of his yearly operations; but where a landlord systematically drains his poor land to increase the rental obtainable for it, his operations require to be conducted on a considerable scale; and then it becomes an important matter with him to have his tile-machines working every second or third day. Tile-draughting, is, on his own estate, with clay dug close at hand? To answer this question has been a matter to which a large amount of ingenuity has been applied. Until about the year 1840, draining tiles were made by hand, enormous arches with a large number of clay pipes were required to perform the work. While, by the invention of the second to the machine, the clay dug close at hand? To answer this question has been a matter to which a large amount of ingenuity has been applied. Until about the year 1840, draining tiles were made by hand, enormous arches with a large number of clay pipes were required to perform the work. Until about the year 1840, draining tiles were made by hand, enormous arches with a large number of clay pipes were required to perform the work. While, by the invention of the second to the machine, the clay dig...
less work by the side of a field, on a capstan which, by
irritable wire rope, draws towards itself a low frame-
work, leaving but the trace of a narrow slit on the surface.
If you pass, however, to the other side of the field, which
is framed as has been said, yet it, been using after it a string of pipes, which—still following the
pipe's snout, that burrows all the white four feet below
ground—twists itself like a gigantic red worm into the earth;
not withstanding the weight, and by being withdrawn, the
capstan, the string is withdrawn from the necklace, and
you are assured that a drain has thus been invisibly formed
under your feet. The machine is worked by two horses;
capstan, firmly and easily fixed into the ground, affords a
firm and stationary support from a great load, an easy
power. The chief defect in the earlier specimens was an
inequality in the level of the channel excavated by the
pipe, because the upper and lower parts being fixed at an
ascending distance apart, any unevenness of the surface was
likeness hidden by an undulating drain below. This defect
was partially remedied afterwards; but the difficulty of
moving horizontally in the drain has continued to be an
develop to the use of this machine. The cost being
considerable, none but a large landowner would find profit
in keeping such a drain, but the use of the drain can easily
be kept up for a month, or other definite period.

The aggregate result of all these various improvements in
its construction and application of agricultural implements
the late Mr. Pacey, in reporting on this subject, as
Chairman of the Exhibition Jury, in 1851, made the following
estimate: That by using lighter ploughs, cultivators that lessen
the necessity for ploughing, drills that economise both seed
and labour-power, horse-hoes instead of hand-hoes, varied
means of management of all kinds, resulting in less
sickness, well-constructed carts instead of clumsy
wagons, fixed and portable steam-engines, steam-threshing
and winnowing machines, turnip and chaff cutters, drain-life
machines, etc., a drain of such a size has been got in
twelve years a quarter of a mile by half the outlay in culivating
a definite amount of crop. It had been rendered further
demonstrable that machinery had given comparative certainty
in agriculture, by enabling many of the operations, in doubt-
ful, invariable and always saving labour. The ploughs,
drills, etc., on which the cost of making and maintaining the
capstan, which could hardly have been done at all by the hand
method.

Mr. Evelyn Denison (afterwards Speaker of the House of
Commons) prepared a Report on the Agricultural Imple-
ments displayed at the Paris Exhibition De L'Industrie, in
1855, in which he endeavoured to estimate the material
waste accruing from the use of machinery in agriculture.
Mr. Sidney, at the close of 1857, gave a few figures intened
to work down the estimate to that year. In this last-named
estimate, Mr. Sidney had followed Mr. Pacey, in recognising
that the returns from the Exhibition—"reported by the late
Mr. Pacey prepared the Great Exhibition report—the land-
owners of the United Kingdom had expended ten millions
sterling in draining two million acres of land, on principles
of long continued experience. But, in estimating the
returns on the items already enumerated, there is that precious,
though not easily-calculated advantage resulting from the
economy of time, by employing machinery at full force
during short intervals of fine weather.

(Report of the Great Exhibition, 1851. Report of the
Parish Exhibition, 1855. Journal of the Royal Agricultural
Agr. No. 564; paper by Mr. Sidney.)

AVERAGES. It can scarcely be said to exist as yet in England. Notwithstanding the acknowledged
importance of exact information as to the amount of our
agricultural production and consumption, especially to
farmers, and the interest that is taken in the subject as shown
by the attention to the Mark Lane reports, which are little
better than ingenious guesses, no steps have yet been taken
to insure a correct estimate of the expected amount of the
incoming crops, and the state of live stock. Such estimates
as are made are derived from individual instances, than
which some more general and reliable results would be of
more service. By this means, calculating, and even of climate in England, make the
application of the doctrine of averages almost more indis-
putable in agriculture than in any other trade. It is by the
arrangement of individual parts that we arrive at something
like a scale. A large piece was made; but the avalanche,
and the more any subject has the appearance of change,
the more necessary it is that the experiences should be
reported, in order to arrive at the law expressed by an
average. The inconvenience and loss occasioned by the
abscence of statistical returns has been often felt. After the
harvest of 1846, the average price of corn for six weeks,
from the middle of August to the end of September, was
45s. 6d., the lowest price in the market since the first of
October. In October, the
price improved; but in November it again fell to 80s. But
as soon as the new year had begun, symptoms of scarcity,
manifested themselves, and the wheat of that same harvest,
which had been purchased by the farmers for about 5d.
anch and a half of quarters, reached the price of 102s. 6d.
per quarter.

In this case, a knowledge of the produce of the harvest
would have saved the farmer from the sacrifice of his
property at the beginning; it would have saved the country
three-fourths of the losses of this harvest, which were
occasioned by a sudden rush into the market for large
supplies; it would have probably saved considerable waste of
food during the period when it was improperly cheap; it
would have saved inconvenience to the foreigners in whose
markets our purchases inevitably increased the price of
wheat; and the gains of the merely speculating corn-dealers
would have been saved to the community.

The desirableness of some knowledge on so important
a subject has led many individuals to form, from the best
and most reliable sources of information, estimates which
show the unreliability of such estimates for any practical
purposes. Some endeavoured to arrive at it by taking the
agriculture of the kingdom, the proportion supposed to be cul-
livated, and the probable amount of produce, by Mr. Gregory King, who wrote in 1665, was among the earliest.
He estimated England and Wales to contain 30,000,000
acres, of which he supposed half to be cultivated. Daven-
port, Grew, Templeman, Sir William Potts, Arthur Young,
Mr. Bees, Mr. Porter, and others, have endeavoured to
make similar estimates varying from 31,648,000 acres, to
46,916,000 acres, which was the estimate of Arthur Young, and was adopted
by Mr. Pitt in his calculations for the probable amount of the income of the kingdom. In 1831, the amount
was stated at 37,834,916 acres, which was very much the estimate of Dr. Beets, who gave it as 38,498,572.
Others, again, have endeavoured to ascertain the consumption by multiplying that of each individual by the number of the population, but here they are materially, varying from 8 bushels to
10 bushels for each individual, an unsatisfactory difference
of one third. We will now enumerate what measures have
been taken in providing statistics by the government.

What are called the core averages, are entries or tables
originally intended to regulate the duty on corn; but if
modified and improved, they might be made an auxiliary to
agricultural statistics. For a century previous to the year
1861, such returns were collected from the principal seaports
of twelve maritime counties—entirely in relation to the
output of the kingdom. In 1861, the collection of these returns was appointed by the magistrates of the town or
borough in which the return was made, but his salary was
paid by the government. In 1821 a change was made. The
returns were forwarded to the inspector of corn, appointed
by the government for the counties of London and
Wales. Every corn-merchant, miller, baker, and maltster, was ordered to make weekly returns to the
inspector. The inspector provided a place for the recep-
tion of these returns; he posted up in some convenient
locality the gross weekly returns, with the average price
of each description of grain sold in the preceding seven days.
These averages were then forwarded to the Comptroller of
Corn Returns, in London, who added up all the gross
returns from all the inspectors, and struck a single price
average for the whole kingdom. In 1832, the collection of
the returns was regulated, as the duties on perfectly
cleared and freed from the admission of foreign corn for home
consumption. When the 'sliding-scale' came into operation,
there were several instances of the averages being tampered
with, in London and some of the other large towns. This
was done by fraudulent persons, with a view of lowering the
rate of duties by fictitious sales of large quantities of corn;
thus swelling the quantity returned, raising the prices, and lowering the duty. In 1848 a motive of economy,
in whether wise or not, was applied to the same end, without any increase of salary, in place of inspectors, as
the latter might die off, for taking the corn averages; and the
returns are believed to have suffered in accuracy from this
change. When the corn laws were repealed, further changes
were made; the returns were made valuable as a basis for
regulation of revenue, in that the returns are, at present,
considered as more accurate.
the agricultural statisticians. The list of towns whence the returns are made has been largely increased; in all the towns thus added, excisemen have been appointed instead of inspectors.

The returns, it is evident, showed nothing beyond the average prices. In 1832 the attention of the government was directed to the attainm't of more satisfactory results. In the previous year, a statistical inquiry had been made by a committee of the magistracy of Norfolk, respecting the state of the county. The committee sent circulars to 625 parishes; but 264 of these declined to answer the questions submitted to them, and the committee had no other resource than to infer from the 462 affirmative returns the 254 negative. Still, though imperfect, it was useful. Mr. Gladstone, in 1832, when the Statistical Department of the Board of Trade was established, Lord Liverpool thought the investigation interesting, and in 1839, when the Statistical Department of the Board of Trade was established, Lord Auckland saw the importance and necessity of obtaining correct agricultural statistics. Nothing was effected, however, until 1836, when the Board of Trade resolved to make a small experiment of its own. Circulars were sent to the clergy of 156 parishes in Bedfordshire, enclosing schedules of the returns required, and asking for co-operation. This experiment was a most signal failure; for out of 156 parishes only 37 returned any answer. It was a time when the clergy and the high Tory party distrusted the suspected radicalism of most new Government projects, and it was on that account an unfortunate period in which to make such a trial. In 1840, Mr. Gladstone, at that time President of the Board of Trade, stated in the House of Commons that the subject was under his consideration. The Board of Trade, the Home Office, and the Poor Law Board, next had a long correspondence in regard to it; and it was found that of these three three might undertake the management of a system of national agricultural statistics; and it appears to have been decided that, as constituted at the time, the Poor Law Board could not adequately fulfill its duty. In 1846 the Board of Trade resolved to make another attempt; and it was ordered that the poor law officers of the three kingdoms—North Hants in England, Mid-Lothian in Scotland, and Ballyborough Union in Ireland. The Irish inquiry was made by a private individual, and was satisfactory; the last inquiry managed by the schoolmasters of the respective parishes, and was equally successful; but the English inquiry was an utter and disheartening failure. The Board of Trade, in this last-mentioned case, addressed communications to the Board of Guardians of the different Unions; while the Poor Law Commissioners backed the application, by requesting the Board to employ their own paid officers to induce the occupiers of land to fill up the schedules that were sent to them. The result was almost nil; scarcely any returns were obtained; and it was stated that nothing less than compulsory powers would be available for obtaining the desired statistics.

The next attempt was made in 1847, when Mr. Milner Gibson, then Secretary of the Board of Trade, brought a Bill to make Provision for the Collection of Agricultural Statistics in England and Wales. By the provisions of that Bill, the duty of obtaining the statistical information was to devolve upon the Registrars-General of Births, Deaths, and Marriages, the superintendent registrars throughout the kingdom to be charged with the appointment of agricultural enumerators in their respective districts; the enumerators were to prepare lists of all the occupiers of land, and the mortgagees of the same; and blank forms to those occupiers, and to collect those blank forms after an interval of fourteen days filled up with the several entries of particulars. This being done, the enumerators were to classify the returns, and construct general tables from them. These tables were to be transmitted to the superintendent registrars, by them to the Registrars-General, and by him to the Board of Trade. These returns and tables were to apply to the month of June in each year. The Bill was a first time; but as the public had not yet learned to feel much interest in the subject, and various party questions were then on the table, the bill shared the fate of many others, and fell to the ground.

In 1854, an attempt was made to obtain complete statistical information. The Government was then in control of the Poor Law Board. The selection was unfortunate, for the impression was instantly received that the returns would lead to additional assessment, and no explanation removed that belief. In addition it was generally feared that such returns would be used against the farmers by their landlords in order to raise their rents, they, in very few cases, holding their farms upon lease. The West Riding of Yorkshire was the only division from which a complete return was procured. In all the other counties the returns were so inadequate as to be useless. Many Unions refused altogether, alleging that their officers had sufficient other duties to perform, and in some Unions up to a proportion of one half, where the guardians had consented, many parishes made no returns. In the West Riding 3,264 parishes were examined, and among them most of the Poor Law Inspectors. Notwithstanding their ill-success, and the many admissions that there was little that could be done in the way of a mere statistical inquiry, the Government was said that would be offered to the investigation of a farmer's affairs by Poor Law officials, the most of them represented that all that was required was a compulsory act; and accordingly the Lords' Committee embodied a series of resolutions in their report, recommending the government to allow a bill into parliament for two returns a year, in July and November, to be carried out by the same machinery. The government however have not yet adopted the recommendation.

Under these disadvantages we will endeavour to give a few of such statistics relating to agriculture as rest upon sure bases. It is quite certain that a rapidly increasing population must have been fed, and that the means of feeding them have been increased; and it is the action of the law of demand for food, and the action of the importation, or from improved cultivation. The following figures will give some notion of what has been effected in each division; unfortunately however, though the inclosures and population only apply to England and Wales, there is no separating the agricultural products of Scotland from that consumed in Scotland. The amount is no doubt very small, for wheaten bread was not generally used in that part of the kingdom in the early periods recorded; and from the vast improvement in cultivation during the latter portions of the century, it will be seen that a very small proportion of the sufficient corn produced in Scotland to supply the population.

The increase of population is taken from between each of the decennial enumerations commencing with 1801. The increase of course of must necessarily decreased, and the best lands will have probably been among the earliest enclosed. Since 1846 the inclosures of commons have been conducted by commissioners, and are passed in acts in groups, in which the whole parish of the land enclosed is the subject of the act; but whole since 1850 does not average more than a few thousand annually, while the population has increased in about the same proportion as in the previous decennaries. The result is a movement of the agricultural products to the south. The whole of the law of dem. The send period in this time the price of wheat on has on the whole decreased. The price of flour with France, from 1800 to 1815 inclusive, the average price per quarter was 84s. 9d. From 1816 to 1890, it was 78s. 4d.; from 1816 to 1830, it was 63s. 8d.; from 1831 to 1840, it was 67s.; from 1841 to 1851, it was 58s. 6d.; in 1852, 50s. 6d.; in 1853, 62s. 11d.; in 1854, 73s.; in 1855, 74s. 9d.; in 1866, 69s.; and in 1870, the highest price reached was 64s. in July, and the lowest in December.

All the statistical returns obtained by Government have a fiscal basis. The only real agricultural statistics we possess are those for hops, of which we know every cultivated acre and every pound of produce; and barley, of every bushel of the crop. The returns for hops and barley are exact; but when, as in the case of live stock, the duty is discontinued, no account is taken by it even of importations, though the Board of Trade in their monthly return give the number imported as obtained from other sources. The following is
the assistance of farmers; succeeded in removing their objections, and convincing them of the advantages; and by means of local branches of the parent institution succeeded in procuring complete returns for the kingdom. These have been continued annually, and through these returns and other information, are the most complete in their details of any yet known. Though the absence of similar returns of England deprives them of much of their value, they are still, conjoined with those of Ireland and the United States, a valuable source of information on the returns for 1866 and 1867. We may presume that the returns are from holders paying a yearly rent of 10l. and upwards (exclusive of tenants of woods, villas, fens, house-holders and the like) in all the counties of Scotland except Ayrshire, Inverness-shire, and Carlisle; and most of the towns of the counties of Perth and Angus, and of Bute which lies in Arran, in both years, and in Caithness, Sutherland, and Orkney, in 1856, where the returns are only from holders paying a rent of 20l. and upwards. Woods, small walks, houses, roads, and waste, are omitted in the calculation.

In 1856 the number of occupiers was 42,919; in 1857 there were 43,432. The number of acres under rotation of crop was 3,045,191 in 1856; of which, of wheat there were 283,592, of barley 165,729, of oats 916,644, of rye 4,030, of bere 15,368, of beans 40,470, of peas 4,617, of vetches 18,231, of turnips 490,131, of potatoes 149,331, of mangold 3,301, of carrots 1,255, of cabbages 1,345, of rape 1,407, of flax 273, of turnip seed 1,759, other crops 783, bare fallow 14,496, and grass 1,378, total 5,672,745. Leaves 1,602 of the total stated unaccounted for. The produce was 2,767,392 bushels of wheat, 5,581,970 of barley, 31,984,361 of oats, 6,560,257 tons of turnips, and 1,439,600 tons of potatoes. In 1857 the number of acres under crop was 3,656,672, of which there were wheat 223,169, of barley 198,387, of oats 938,613, of rye 5989, of bere 21,607, of beans 39,156, of peas 2867, of vetches 18,415, of turnips 475,501, of potatoes 139,919, of mangold 3,529, of carrots 1,401, of oats 303,912, of calves flax 1,634, of turnip seed 2,576, of other crops 777, of bare fallow 18,582, and of grass and hay in rotation 1,498,805, an excess of 999 acres over the stated total. The produce was 6,154,800 bushels of wheat, 6,343,034 of barley, 27,670,763 of oats, 6,938,160 tons of turnips, and 430,452 tons of potatoes. In 1856 the total number of horses was 179,833, of milk cows 209,960, of other cattle 475,364, of calves 197,709, of sheep and lambs 5,165,560, of swine 125,924. In 1857 the numbers were, of horses 185,429, of milk cows 303,912, of calves 195,198, of sheep and lambs 5,883,168, and of swine 140,324. In this account the horses, cows, and swine kept in towns are not included; and it is estimated that above 300,000 head of stock, and upwards of 200,000 acres of tillage are not included in the returns. These returns, it is true, do not show the greatest proportional acreage in wheat and in white crops generally, and Aberdeen and Argyle the greatest in turnips; those counties also possessing the greatest number of live stock.

In Ireland, where the interest felt might have been supposed to be less, statistical returns have been obtained in an excellent form, and with no opposition. The task of gathering the returns was confided to the statistical in 1856, and they have been continued annually since. We append the return of 1857:—In that year the returns show that there were 5,680,089 acres under crop, being an increase of 106,542 acres over the quantity in 1856. Of these 626,851 acres were in wheat, 1,570,076 in oats, 2,425,257 in barley, 1,537,036 in beans, peas, flax, and vetches, a small fallow of 1,480,000 acres, and a general, but a decrease of oats on 58,039 acres. On green crops there was a general increase of 45,637 acres, potatoes occupying 1,144,930 acres, an increase of 43,216 acres, and flax had decreased from 106,311 acres in 1865 to 90,074 acres in 1857; and turnips had decreased 4,487 acres. Meadow and clover had increased from 1,302,787 acres to 1,369,421 acres.

The produce of the 5,753,681 acres in cultivation in 1856, had been 2,735,193 barrels of wheat of 20 stone each; 3,775,045 barrels of barley of 16 stone each; 60,700 barrels of barley of 16 stone each; 72,156 barrels of rye of 20 stone; 431,661 bushels of beans and peas; 35,288,345 barrels of potatoes of 20 stone each; 1,145,281 tons of turnips; 325,650 tons of cattle; 3,066,553 tons (14 lbs.) of flax; and 3,492,732 tons of hay. The total number of holders of land was 692,498; of whom 36,474 held not more than one acre; 88,035 not more than five acres; 179,951 not more than fifteen acres; 192,455 not more than fifty acres.
thirty; 71,156 not more than fifty; 63,379 not more than one hundred; 21,293 not more than two hundred; 2943 not more than five hundred; and only 1655 held upwards of fifteen hundred acres.

Live stock, except sheep, had increased remarkably. The number of horses was 600,693, an increase of 27,395; the number of cattle 3,618,544, an increase of 30,686; the number of sheep 3,446,076, a decrease of 24,618. Pigs numbered 1,252,105, an increase of 256,657.  

Produce ships in Ulster are required to keep the road-sides and fences free from weeds, and surveyors in the other provinces are recommended to obtain authority from grand juries, etc., to enforce in them similar regulations.

Many foreign colonies have found the advantages of having statistical returns of their agricultural produce. Austria, Prussia, France, Denmark, Hungary, Belgium, and the United States of America, have all such returns more or less perfect, among which those of Belgium take a high rank, and are nearly equal to those of Scotland. Such statistics for the whole of a kingdom are highly valuable for the regulation of the inhabitants of that kingdom; but if we possessed them for the whole of the civilised world, what are called the chances of agriculture would probably be reduced to a certain and the price of food would remain with little or no variation.

AGRODROMA. [ALADDINE, S. 2.]

AEGRESTEMMA (from "agro", a field, and "temna", a crown), a genus of alyceae, is a kind of Cerealia. It appears in the order Caryophylloideae. It has several species, the best known of which is the Corn-Cockle, which is now referred to the genus Lychnis, or Gilboa.

AHU [COUNCIL OF].

AIGUILLON. [LOT-et-GARONNE.]

AIKIN, ARTHUR, the eldest son of John Aikin, M.D., was born in 1784. Arthur Aikin began his literary career, we believe, as editor of an annual called the "Limean" this was a page of the first six volumes of which—1803-1808—his name appears as editor. His earliest scientific work was ‘The Manual of Mineralogy,’ of which the first edition was published in 1814. Besides these he was the author of a ‘Tour in North Wales,’ a ‘Dictionary of Chemistry and Mineralogy,’ and a ‘Dictionary of Arts and Manufactures;’ and also of numerous papers in various scientific journals. For a long series of years Mr. Aikin was the resident secretary of the Society of Arts, and a frequent contributor to its ‘Transactions.’ He was also one of the oldest followers of the Linnean and Geological societies. Mr. Aikin was a map of quiet retiring habits, and outlived his scientific reputation; but was well known in scientific circles as one of the most regular and assiduous attenders at the meetings of the metropolis, and was generally esteemed. He died at his house in Bloomsbury, London, April 16, 1854, in his 81st year.

AIRA, a genus of Grasses belonging to the tribe Sclerenteres, and of which the best known species, A. canescens, the Tufted Hair-Grass. It has long and flat leaves, with a fibrous perennial root. It flowers in the beginning of August, and reaches a height of 12 or 15 feet. It grows naturally on marshy damp soils, in the form of large tufts. It is a wiry harsh grass, and is rejected by domestic animals. It may, however, be advantageously sown as a cover crop, or by the side of manure-harvests for swine and wild fowl. (Lawrence, Acrographia.)

AIRE, RIVER. [YORKSHIRE.]

ALTONIA (after Mr. W. Allon, for many years head-gardener at Kew) a genus of plants belonging to the order Melaceae. The A. concinna is a native of the Cape of Good Hope, and is cultivated in our greenhouses.

AKHALZIKH, a town in Russian Armenia, situated near the watershed between the Black Sea and the Caspian, on a few miles from the Perenagh Dagh, in 41° 40' N. lat., 43° 10' E. long. Population about 15,000, who are chiefly Armenians. It was formerly the chief town of a pashalik in Turkish Georgia; since thecession of which province to Russia, it is the capital of the province.

Among the buildings of the town are the mosque of the eldest of the califeh at the mosque of Ahmed, which is built on the model of that of Santa Sophia at Constantinople. Connected with the mosque is a college, and a library rich in

Oriental literature; but it is said that the best works it contained have been carried away to the royal library of St. Petershurg. The Armenians have several large churches, and there is also a synagogen. The chief trade is in silk and wool. There is some trade in wine, and the town lies on the road between the port of Batoum and Tiflis, being 80 miles E. from the former and 105 miles W. from the latter.

AGOAS, a province o f Brazil, which, up to about 1840, was a district, or comarca, of the province of Pernambuco; but, on account of its increasing population and wealth, was formed into a separate province, which is under the administration of its own governor. It is situated between 9° and 20° 3' S. lat., and 35° 30' and 42° 40' W. long., on the south of the province of Seregipe del Rey, from which it is separated by the Rio de San Francisco, along the northern banks of which it extends to the great cataract, called Cachoeira de Palmo Afsom. On the west and north it is surrounded by the province of Pernambuco, from which it is separated for a considerable space by the Rio Unna. The Atlantic washes its eastern side. In length, from east to west, it extends about 150 miles; its average width probably does not exceed 60 miles. The area is about 900 square miles.

Two-thirds of this surface are covered with mountains. They form the southern declivity of the elevated and hilly table-land, which occupies nearly the whole of the country, and is intersected by a series of broken mountains. These mountains come close up to the river San Francisco as far east as the mouth of the Rio Sacare, and terminate in Alagoas, at a distance of about 20 miles, or little more, from the sea. This region is almost entirely covered with wood, and is traversed by numerous rivers, which afford a considerable article of exportation. The valleys and more gentle slopes of the mountains exhibit a considerable degree of fertility. Along the eastern base of the mountains export products to the river, and to the sea. Though it is little wooded, it is covered with a light soil, very rich for the culture of cotton, which is extensively raised. The country along the sea-shore, and at a distance of about 10 miles of it, is covered with the best alluvium, which has been brought down by the numerous small rivers that rise on the eastern declivity of the mountain-region, and deposited along the edge of the inundating tract. This soil is of the best quality, and fit for the cultivation of every kind of intertropical productions. A considerable portion, however, of this tract is still covered with swamps, and the tide, which rises along the coast from 3 to 5 feet, enters the mouths of the rivers, and has changed the adjacent surface, forming a great number of lakes and lagoons. The larger lagoons is the Lake of Mangua, from which the river Alagoas runs to the sea in a southern direction. It is stated to be 30 miles long, and about 3 miles wide at an average, and consists of two lagoons united by a strait. The northern lagoon is the port of Sambod, and the southern, which has its water is salt. Only canoes can navigate the river Alagoas, which carries its water to the sea. The rich plantations situated around the Lagoa do Sul carry produce to the northern lake and the town of Alagoas, whence it is transported to the harbours of Taranga and Pajamsar. Farther south is the Lagoa do Siquilhas, which is 15 miles long from north to south, with an average width of 3 miles. A river of the same name runs southwards to the sea. The country along the coast which lies to the west of this coast is small, and have bars at their mouths, with so little water on them that sea vessels of even the smallest size cannot enter them, the province has a few harbours sufficiently deep for vessels of moderate magnitude. The most northern are the harbours of Pajamsar and Taranga, which are close together and separated by a low tongue of land. The port of Taranga is the better of the two. Merchandise disembarked at this port is transported by land three miles to the Lagoa del Rey, by a splendid road, situated just to the northeast of the town of Alagoas. Curriphe, which is farther south, is a harbour of moderate size, formed by a reef extending to a distance of 300 yards from the shore, which breaks the fury of the sea. The harbour may be entered by two breaks in the reef, but vessels of over 10 tons cannot enter. Waters are deeper here into the sea bears the same name, and is navigable for canoes for several miles, but has very little water on the bar at its mouth.  

The only river which here deserves to be noticed is the
San Francisco, which enters Alagaoas at its western extremity at the great cataract of Paulo Afonso, where it is said to descend 50 feet in perpendicular height. It then runs for many miles to the left of the Alacundo, forming several small and smaller cataracts, between rocky banks several hundred feet high, and extremely rugged. Many rocks occur in the bed of the river, and it is not navigable. At Caninde the width of the river increases to half a mile and more. There, as the banks are of moderate height as far down as Penedo. Below Penedo the river enters the alluvial tract, in which it divides into several branches, forming a great number of islands, generally low and abounding with woods. They have a thousand varieties, which are all worked by using sun, fire, and vegetable acids. The banks are raised in abundance.

Bark, mastic, copaiba, and timber-trees, are abundant. It is said that the trees of many species of beans, like the massar, are rare. They are abundant near the mouth of the river. The fertile coast among these trees, is so extreme that mountains can enter it only at high-water, and must there wait for the full tide to go on. They can sail as far up as Penedo, 25 miles from the mouth. Father up the navigation is solely by ajoes, that is, two or more canoes moved together with cross-pieces of timber. In ascending the river sails are always used, as the wind from eight o'clock till the following morning's dawn blows always from the east. The ajoes always descend the river with the current, which is rather rapid. The width of the river at its source is about one mile, and in the rainy season is frequently oppressive, except along the coast, where it is moderated by sea-breezes. It is less hot in the dry season, and also more healthy. The wet season occurs from November to March, and then the rains are very abundant, but showers are not rare in the dry season also.

Tobacco was once the staple article of this province, and was especially sent to the western coast of Africa; but since the abolition of the slave trade this branch of agriculture has entirely been decreased. Tobacco may be replaced by sugar and cotton, which at present constitute the staple articles, the first being raised in the alluvial and the second in the inundating tracts. As food are raised—mandioca, maize, rice, plantains, beans, and some roots, as yams, sweet potatoes, &c. but the chief dependence of the province is on the fruit-trees, cacao-nuts, and palms. The cacao-tree is carefully cultivated in some districts on account of its oil, which affords as article of exportation. Alagaoas has extensive forests of timber-trees, even in its lower districts, and affords the best timber in Brazil. It is exported to Bahia and Recife; and many small vessels are built in the province. Some of these timber-trees are very durable, especially those named sengupira, fareno, vinbatico, and tacho, but their wood affects the ship's timber. The houses of the fazendas are all built of wood, and are marked from the great quantity of tannin contained in the wood. The forests abound also in several kinds of wild fritters, and there are also the trees which produce drunk's blood, maistic, specchunias, cuphea, and cacachoe. Other trees abound of the same character. Brazil-wood is the most prized. An inferior species of quinine, or Jesuit's bark, is not rare.

The European domestic animals are far from being numerous, except asses and mules. The oxen exist at present only in the mountain-districts. The most numerous animals are deer and monkeys of different kinds, and also ant-eaters, smallsquirrels, and others. The tapir and peccary are rather rare. Alligators abound in the lakes and rivers; land-lizards are not numerous, but they are very great, especially of parrots. Honey and wax are obtained from wild bees. Several kinds of fish abound in the lakes and lagunes, and on the sea-coast, and they constitute one of the principal articles of food for the lower classes and negroes. There is a great and rather short and strong, the upper mandible being strengthened without any notch, and not longer than the under. The nostrils, situated at the base of the bill, are olong, and protected by small plumages and bristles directed forwards. The feathers on the sides of the head can be raised up at the will of the bird into the form of a crest.

Agriculture is the principal occupation of the inhabitants. Only a few persons are employed in the exercise of the most necessary arts of civilised life. Common cotton-cloth is made in the fazendas, but the manufacture of good goods is imported. Boat-building is the most important branch of industry.

The province returns two senators and five representatives to the imperial parliament. In this province is one city, Alagaoas, and seven towns, namely, Porto de Pedras, Porto Caleo, Mateayo, Anadia, Atalaya, Pousim, and Penedo. Besides these places, there is San Miguel, which is built about 10 miles from the sea, and is a populous place in a very fertile district. The village of Caninde, on the Rio de San Francisco, is the place where the navigation of the river terminates. Goods destined for the consumption of the country adjacent to the upper course of the river are here disembarked, and transported on the backs of negroes a few miles to the tributaries, which are about 30 miles distant, and built where the cataracts begin. They are again embarked, and carried in boats to the places of consumption.

A railway has been projected from Pernambuco to the cataract of Paulo Afonso, which will pass through the best part of this province, and connect the country along the San Francisco with the important city and port of Pernambuco.

(Henderson's History of Brazil; Spix and Martinis Reise in Brasilien.)
of a grayish white, with specks of a brown colour. They frequently rear two broods of young during the summer.

3. Some remarks on the Skylark, for which there are many in Britain, where some remain during the winter, the greater number flock together and migrate, either southward or to the sea-coast. During these migrations immense numbers are caught in nets for the table, particularly on the continent, where small birds are more sought after for this purpose than in Britain.

Localities.—Europe and America.

Mr. Swainson considers this as the Fisistrous type. Examples are—Alauda africana, for the S. coast of Africa; A. montana, for the E. coast of Africa; and A. australis, for the S. coast of South America. The Skylark is placed in C. lengthened to equal, A. Alouetta cinerea, and A. alouettæ des Charmes of the French; and Loloa, Lodoa Canarias, Lodoa de Passy, and Lodoa de Montagna of the Italians; and Lodoa Sericata of the Germans; and Skylk (Scotch Lowerv) of the modern British.

The Skylark is well known, from its inexpressibly beautiful song, chanted forth far up in the air when at liberty and in its natural state, to require any description. Food.—Insects and their larvae, with many sorts of seeds and grain.

Notes.—On the ground. Eggs four or five, greenish white, spotted with brown.

Localities.—All the parts of Europe; also in Asia and the northern parts of Africa, but not the south of the vast continent (Temm.); the whole of Europe within the temperate zone, many parts of Asia, and the north of Africa. (Selby.)

Calendula. (Linn.)

Bill thick, much compressed; the column curved and convex; the commissure arched; the tip of the upper mandible wide and inflexed. Wings long or moderate; the first quill very small and spurious; the second nearly equal to the third and fourth; lesser quills short, emarginate. Tail slightly forked. Lateral toes equal. The Denticroto type—C. magnirotiro, *Ois. d'Aftr.*, pl. 192. (Sw.)

Subgenera—Myopora, Horst. Bill as in Calendula. Wings short; rounded; greater quills hardly longer than the second; four toes, the first longer than the half length of the second, which is shorter than the third; the third, fourth, fifth and sixth, equal, and longest. Tail short, even. Legs long—*M. Javanica*, 'Linn. Tr.', xii. 159. (Sw.)

Bracomyza, Sw. (Brachomyza.)—Bill as in Calendula. Hinder claw very short. Wings and tarsi much lengthened. Africa. (Sw.)

Agrodrus. (Sw.)

Bill slender, considerably compressed; both mandibles of equal length; the tip of the upper not reflected over the lower, and with a small notch, almost obsolete. Wings long; the first four quills nearly equal; the rest rapidly diminishing, and emarginate at their tips; tertials lengthened, preceded by the middle quills. Tail moderate, even. Legs pale, long, slender. Tarses long, slender. Lateral toes equal, but the outer claw shorter than the inner. Colour brown, lark-like. Distribution universal. The pre-eminent type—*Agrodrus refractus*, *Enl.*, 691, f. 1. (Sw.)

Macronyx. (Sw.)

Bill slender, compressed, thrush-like, entire; nostrils large, naked, the aperture lateral. Wings short; the pri-

**Fossil Larks.**

Dr. Buckland figures a lark (Alauda) among the land Mammifers and Birds of the third period of the Tertiary Series, in the first plate of the illustrations of his 'Bridge-

and between 153° and 162° 40' W. long. It is more than 30 miles long, and opposite the mouth of the river Nahnek (157° W. long.) 110 miles wide, but its breadth decreases in proceeding farther west, where in some places it is hardly 90 miles wide. It terminates at the strait of Innassak, which separates it from the island of Cominak.

The two coast-lines differ greatly in aspect. The southern shores rise with a steep ascent, are indented with numerous inlet and bays, and lined with numerous islands, separated by water, some wide and others quite close together, and in some places extending to a distance of ten, and nowhere less than five miles from the coast. Between these islands and the coast the sea is commonly very deep. The northern shores are much more elevated. When his term of service was over, he went to Sandy Beach, and has only a few open bays, but it is free from the inlets and shoals, and offers in many places an encampment of moderate depth. A chain of mountains extends through the peninsula from the strait of Innassak to the limits of Illamna along the south-eastern shores, but east of 158° W. long., its highest part is at a greater distance from the coast than to the west of that meridian. It contains several very elevated peaks towards its western extremity, and four at least are always covered with snow, but have no glaciers.

It is remarkable that in the western and more elevated portions of the chain, which consists mostly of volcanic rocks, and where some still active volcanoes exist, there occur four large lakes. These contain the water that accumulates in a sandy beach, and has only a few open bays, but it is free from the inlets and shoals, and offers in many places an encampment of moderate depth. A chain of mountains extends through the peninsula from the strait of Innassak to the limits of Illamna along the south-eastern shores, but east of 158° W. long., its highest part is at a greater distance from the coast than to the west of that meridian. It contains several very elevated peaks towards its western extremity, and four at least are always covered with snow, but have no glaciers.

The coast is indented with a number of bays, which are filled up by sand in the process of time. The low country along the Bay of Kalakoo consists mainly of sand, covered in many places with swamps, and in others with marshes. Their growth on it, and abundance of dwarf willow and alder, but no trees. Along the southern coast, especially east of 158°, also occur some level plains at the innermost recesses of the bays; they do not much differ in places from the sand but are covered with enormous forests, and the vegetation is much more vigorous, and the bushes attain a greater height. The best harbour on the north-western shore is in the Bay of Moller (56° N. lat., 160° 40' W. long.), between which and the Bay of Pavlovskaia the peninsula is separated by a strait of about 4 miles. On the south-eastern coast several harbours are met with. The most considerable from east to east are Morjewskaia, Belowskaia, Pavlovskaia, the Bay of Wrangell (150° W. long.), the best of them all, and Bay of Kamtschatka.

The Russians have found among the natives of both shores, introduced agriculture, and though no kind of grain succeeds, the inhabitants of the few dispersed villages raise considerable quantities of potatoes, and in some places they have introduced rye, one of which their principal subsistence from fishing, the sea abounding in cod, seals, turbot, and several kinds of molluscs. Whales are frequent along the northern coast, but rather rare on the southern. Morses in immense numbers visit the northern coast, and their teeth constitute the principal article of commerce, since the sea-otters, which formerly were very plentiful, have been nearly destroyed by the avidity of the inhabitants. Reindeer, bears, and red foxes, are the only large animals which are found in great numbers, but towards the east they are very scarce, and perhaps if the musk-ox. Seals and sea-lions visit the deeper inlets, and afford to the inhabitants some additional articles of commerce.

The number of settlements made on this peninsula does not exceed ten. Those west of 155° W. long. are dependent on the establishment of Onalashka, and those east of it on that of Kodiak. The largest of those settlements is the town of Kattalekoi, on the Bay of Kattal, which has 90 inhabitants.

The number of settlements made on this peninsula does not exceed ten. Those west of 155° W. long. are dependent on the establishment of Onalashka, and those east of it on that of Kodiak. The largest of those settlements is the town of Kattalekoi, on the Bay of Kattal, which has 90 inhabitants.

Alkantoa, a genus of plants belonging to the natural order Apocynaceae. It was named after Frederick Allaman, a surgeon who travelled in Guiana, in 1769, and afterwards A. Russia. He was a correspondent of Linnaeus. The species of this genus are shrubs yielding a milky juice, with verticillate leaves, and many-flowered peduncles of large yellow flowers. They are worthy of cultivation on account of the beauty of their flowers and foliage. They are all natives of South America, and when cultivated require a strong moist border to grow freely. An infusion of the leaves of A. cathartica is said to act as a powerful purgative, and an overdose to produce poisonous effects.

Allan, Sir William, was born in Edinburgh in 1793. After receiving his early education at the High School, he was placed with a coach-painter, but displaying a strong attachment to art, he was entered as a pupil in the Trustees' Academy, where Willie was his fellow-student. He returned to his native town, and became a student of the Royal Academy. In 1805 his first picture of a 'Gipsy Boy and Ass' appeared at the exhibition of that institution. Not succeeding in at once attracting public attention, Allan resolved to try his fortune abroad, and selected St. Petersburg for the scene of his experiment; incited partly, it is said, by the expectation of finding novel and picturesque objects for the exercise of his pencil. He remained in Russia nearly ten years, making occasional journeys to distant parts of the country, to Turkey, Tartary, the shores of the Black Sea, &c., and voluntarily employing himself in gathering materials for his art.

On his return to Scotland in 1814, he made a public exhibition of his pictures, and finished painting the Russian, Tartarian, and Circassian scenes and costumes. Among the pictures was a large one of 'Circassian Captives,' which at the suggestion of Sir Walter Scott was purchased by one hundred gentlemen, who subscribed ten guineas each; it fell to the lot of the Boy and Ass. In 1819 he returned to Scotland, and for several years was mostly engaged in illustrating the history or the romance of Scotland. To this period belong the 'Murder of Archbishop Sharpe,' 'Parting of Prince Charles Stuart and Flora Macdonald,' 'Knox Admonishing the Mary Queen of Scots,' 'Murder of the Regent Murray,' and others of his best works. In consequence of a disease in the eyes he was compelled for a year or two to cease from painting, and being advised to try a change of climate, he visited Italy, Austria Minor, and Greece. On resuming his pencil, his 'Slave Market at Constantinople,' and pictures of a like kind, showed that he had profited by his travels.

Meanwhile he had been gaining the distinctions awarded to success in his profession. In 1820 he was elected a member of the Royal Academy. In 1830 he was President. In 1836 he was elected a Royal Academician. In 1838 he was elected a Fellow of the Royal Society. In 1840 Allan was appointed to succeed him as President of the Society of Painter in Water-colours, which is the highest honour of knighthood. Sir William Allan was best known by his Russian and Circassian genre pieces, and by his Scottish historical works. In all of them there is much skill and refinement, but in none any very evident marks of a high order of genius. But he was also a very successful painter of a special class of portraits, such, for instance, as his 'Scott in his Study Writing,' and its companion, 'Scott in his Study Reading,' in which his genius is most completely displayed. His pictures of the Battle of Waterloo, which met with the marked approval of the Duke of Wellington, and of which his grace purchased; the 'Battle of Preston Pans;' 'Nelson Boarding the San Nicholas and Bannockburn,' a large painting, on which he was engaged at the time of his death. One of his last considerable works, 'Peter the Great teaching his Subjects the Art of Ship-building,' was a commission from the Emperor of Russia.

Sir William Allan died on the 23rd of February, 1850. As a painter he was generally acknowledged by his countrymen to be at the head of Scottish art, by right of his talent as well as of his industry.
follow the same profession. Having completed his education at St. Paul's school, he for a time practised as an usher in Tavistock, near where he was more advanced he had for a long period to manufacture paintings for picture-dealers. Under the necessity of producing many showy pictures at low prices, he soon acquired considerable mechanical dexterity, and he was led not unnaturally to turn his attention to scene-paint- ing. He painted some pictures for the London Royal Academy, working for a while as assistant to Stanfeld and others, and he obtained the situation of principal scene-painter at the Olympic Theatre, when that establishment first came under the management of the late Mr. Vandyke. Allan's art, his artistic style and good pencil did much to secure the success of the brilliant spectacles which formed the distinguishing feature of the management. Allan's early oil-paintings were generally of small size, and represent quiet, homely, pastoral scenery, which was rendered with great delicacy, and a nice appreciation of the freshness of natural colour. But though they found purchasers among well-known patrons of art, his reputation extended slowly, and he attributed his tardy progress to the placing of his pictures at the annual exhibition. He painted for the newly-founded Society of British Artists, and became one of its most ardent supporters. All his most important works were therefore exhibited in the first instance on its platform only, and consequently became his key pictures.

Allan did not attain the position his early pictures promised. His inclination and his forte lay towards pastoral scenery. He loved and he could well depict those fresh, open, country scenes, so characteristic of our home counties, which Milton describes as affording constant delight to the city dweller. For these Allan had all a Londoner's relish, and while he painted them with continual reference to the reality, his pictures commanded the sympathy of all who enjoy this style of art. But when he had a chance of indulging in it, he turned his attention to various scene-paintings, which are so attractive in conjunction with gas light and theatrical properties, he began to employ them in his pictures, and though he succeeded by such means in sparing himself much thought and labour, while he rendered his pictures more attractive in the exhibition-room, it was at the expense of those higher qualities of truth and propriety which are essential to lasting fame. And the evil was fostered and strengthened by another influence under which he laboured for some time; he attempted to paint real scenes and more with a special regard to them. His earlier pictures have many admirable qualities, and his latest display great technical and manipulative skill; but his life was not one of artistic progress, and his is not a name that can permanently take a high place among the artists of England.

Allen died August 26, 1855, of disease of the heart, at the early age of 49; leaving a widow and eight children, for whom unhappily he had not been able to secure a sufficient provision.

ALLOXAN, ALLOXANIC ACID, ALLOXANTIN. [CHEMISTRY, S. 2.]

ALLYLE. [CHEMISTRY, S. 2.]

ALMADINE. [GARRET.]

ALPINA, a genus of plants belonging to the natural order Zingiberaceae. The species have thick tuberous horizontal roots, which are internally mucronate, with thick corolla- ceate leaves, having a silt glutinous sheath. The flowers are in panicles, or loose racemes or spikes. The tube of the corolla is short, the inner limb 1-lipped. The filament of the stamens linear. The fruit is capsular and 3-celled, with very few seeds.

A. Galangana is a native of Sumatra, and is cultivated in the Indian Archipelago. Its roots are pungent, acid, and aromatic, and are often substituted for ginger. They are sold by druggists under the name of Galanga major. A plant related to, if not identical with, the A. esculata of

Linnaeus, is called Coromandi in British Guyana, and is described by Dr. Hancock as a bitter pungent plant, and when boiled has a strong acrid and diuretic, and in large doses as emetic. [GALANGA.]

AM, a district in Kurdistan. The town is situated upon a lofty isolated rock in 36° 47' N. lat. 43° 21' E. long. in a plain which is screened on the north and south by mountain-ranges and drained by the Ghar River, which flows southward into the Tigris. The town range called Ghar is thickly wooded, and in parts precipitous and very difficult of access. It separates the Amidiyah district from the country of the Miskoit Kurds. The northern range, which is also well wooded but seems to be so high as the southern part of the plain of Amidiyah from the extensive valley of Berwari.

The plateau of Amidiyah is cut up into innumerable ravines by the torrents which rush down the mountainous into the Ghar River, by which they are carried to the Zab. It is well wooded with the gall-bear and oak and with the fruit and forest trees. It contains many villages, which were formerly inhabited by Chaldean or Nestorian Christians and were very flourishing, but many of them have been deserted by the inhabitants in order to escape the violence of the Kurds and Turks; and those that remain have joined the Roman Catholic Church. Around the town and the villages are well-cultivated gardens and orchards. Tobacco, rice, grain, water-melons, fruit, and gall-nuts are very plentiful in the country. Kerr, in his Agriculture, lays down that it was previously affording little encouragement to cultivate the land.

The town is described by Dr. Layard as a heap of ruins; porches, basseas, baths, and habitations were laid open to their immemorial recesses; every part seemed crumbling to ruin, and nearly deserted; for the population at the time of his visit, in August, had retired to their summer habitations in the mountain valleys. The fort or castle, which is surrounded by walls flanked with towers, is considered of great importance as a key to Kurdistan and is defended by a garrison of 300. The fortress and Turkish and Kurdish influence have considerable importance and strength, and contained a very large and flourishing population. It was governed by hereditary pashas, who traced their descent from the Abbasides, and were on this account always regarded with religious respect by the Kurds. The ladies of their family enjoyed the title of Khan. Ismail Pasha, the last of these hereditary chiefs defended himself long against the Turks in his inaccessible castle, but at last a mine was set beneath the fort, which was set on fire, and the castle itself was consumed. Under the present pashas the fortress is safe from attack, and the place was taken by assault.

Amadiyah (which is said to mean 'Town of the Medes') is frequently mentioned by early Arab geographers and historians, and its foundation most probably dates from the time when the Medes were subdued in B.C. 518, and it was called Batalana. To a defaced bas-relief on the rock near the northern gate, Dr. Layard assigns the date of the Aegacian kings. Amadiyah is proverbially unhealthy. Fever and agues are very prevalent in summer, at which season the population remove to the neighbouring mountains, in the valleys of which they live in tents and osuils, or sheds made with boughs. The population has greatly diminished since the place became subject to the Turks.

Dr. Layard's Minnie and the Remnants; Colonel Cheshy's Expedition to the Euphrates and Tigris, &c.

AMALFI. The story of the discovery of a copy of the Pandecta at the siege of this place, a.d. 1137, is now considered entirely without foundation. (Savigny's Geschicht des Römischen Rechts im Mittelalter, Heidelberg, 1815, 6 vols. 8vo.)

AMAND, Sr. [CHEM.]

AMBLEVE, the Savoy name of the Mezlar, a genus of plants belonging to the sub-order Pomaceae (Pometia), of the order Rosaceae. It has 5-cleft calyx with lanceolate petals, and an ovary of 10 cells, with a solitary ovule in each. The mature fruit is 5-celled, with one seed. It seems to be a species of the stuffed deciduous leaves, and racemes of white flowers.

A. vulgaris, the common species, is a native of rugged places throughout Europe. It is the Aetoma rotundifolius of Pers.”

A. Botryopus, the Grape-pear or Canadian Medlar, is a

Digitized by Google
very common plant in Canada; it is also a native of New-
tisland, Virginia, and the higher parts of Columbia. It is
found wild in Europe, and cultivated for the sake of its
garden varieties. A. scusa is also a shrub 6 or 8 feet high, and is a native
de North America, throughout Canada from Lake Huron to the
Saskatchewan and Mackenzie rivers, and as far as the
Rocky Mountains. Sir John Richardson says that it abounds at
those places, and is highly serviceable as a food for
dogs. It is also much used by the Indians for making arrows and pipe-stems, and is thence
tumed by the Canadian voyageurs 'Bois de Flêche.' Its
flowers, about the size of a pea, are the finest fruit in the
country, and are used by the Indians both for food and
medicine. They make a very substantial addition to pemmican,
and excellent puddings very little inferior to plum-pudding.

Another North American species is known by the name of
A. enneasquama. Its fruit is of a blood-red colour.

The Asimines, which are the species of A. enneasquama. possessed by the Superior Courts of Law have been greatly extended
by the Common Law Procedure Acts of 1832 and 1844; and
both of which expressly require that all amendments shall be
made which are necessary for the determination in the ensuing or
the question in controversy between the parties.

**AMERICA.** In the article AMERICA, in the 'Penny Cyclopaedia,' the narrative of discoveries terminates with the
voyage of Captain Ross (afterwards Sir John Ross), in search of
the North-West Passage, and there he made a northern passage, without
return till 1833. He was forced to pass four successive
winter in the dreary regions of Boothia Felix, and emerged
with his crew from the icy seas when the hope of return was
almost universally abandoned at home. The
expedition took the title of the basin of the
Large North-West, through the munificence of Sir Felix Booth, a London
ddler, some additions were made to our stock of geo-

The expedition was sent out in 1833 on a land journey in search of the
pre-
ceeding expedition; and he traced the Back River, named
him. Having returned in 1836, he was again appointed
the commander of an expedition in 1838, which was destined
to proceed to Wager River and Repulse Bay. This was a
most disastrous voyage, the expedition having to pass the
winter in the ships tossed about in the ice. No geographical
results were gained. During the years 1836 to 1838, Deas
and Simpson, two officers of the Hudson's Bay Company, sur-
ted the Great lakes and Territories in the western
American continent, leaving only the southern part of Boothia
fjord, of the entire coast line, unexplored. This latter portion
was surveyed by Dr. Rae in 1848. In 1846 one further
expedition started under Dr. H. Imlay, that sailed from the
North-West Passage, when the expedition under Sir
John Franklin was despatched to Lancaster Sound. The
expeditions which have been sent out in search of Sir John
Franklin and his associates, and the discoveries which have
been made in the Arctic Regions, are described in the articles
North-West Passage, S. 2., and Polar Countries and
Straits, S. 2.

The progress of discovery and settlement in the territories
of the United States has proceeded without interruption, and
new States and Territories have been established since the
article AMERICA was written, which are described under their
respective names in the two Supplements. Among the
discoveries which have enabled the government of the United
States to extend its possessions, none are more important than
a discovery made by Lieutenant Fremont in his exploring expeditions of 1842,
1843, and 1845. The tides of emigration have since swept
the east to the west through the passes of the Rocky
Mountains, and the country has been opened up from
Mexico, and the important State of California, and
town of San Francisco with its capacious harbor, estab-
lished on the shores of the Pacific Ocean. The
discovery of gold in California has led to many important explo-
ations, the Sales of lands throughout the Territories have been carried out,
and the territory of Utah added to the United States, on the
western side of the Rocky Mountains. On the eastern side
aircraft have been formed in various directions to the extent of
more than 20,000 miles; and several important exped-
tions have been dispatched, by order of Congress, to discover
the best route for a railway from the Mississippi to the
Pacific between the parallels of 38° and 49°. These expe-
ditions, conducted by gallant and skilful leaders, have contributed very largely to American geo-
ography, observations having been made from the Mississippi to the
Pacific, between the parallels of 49° and 47°, 41° and
and near those of 38°, 36°, and 35°, touching upon the
Marquesas Islands, and to the north of San Pedro and San Diego. On the results of these labours the Secretary of
War has reported, that "the route of the 32nd parallel is, of
those surveyed, the most practicable and economical route
for a railroad from the Mississippi River to the Pacific
Ocean."

In British North America, an extensive region, including at
least 112,000 square miles, remains almost completely
unexplored. This region extends from the ocean to
the foot of the Rocky Mountains, and from the
northern branch of the Saskatchewan to the
parallel of 49°, which forms the boundary between the British
possessions and the United States. The expedition of
this portion of British America has been undertaken by Mr.
Palliser, a traveller who has spent a considerable time in
the neighbouring districts of the Upper Missouri. For the
purposes of this expedition the Lords of the Treasury, on the
recommendation of the Secretary for the Colonies, have
made a grant of £50,000 to Mr. Palliser, and Lieutenant
Blakiston of the Royal Artillery, Mr. Bourgeois as a guide,
and Dr. Hector a medical gentleman, have been associated
with Mr. Palliser. The chief objects of exploration are
stated to be, 1, the exploration of the water-parting between
the Missouri and Saskatchewan rivers; 2, the
exploration of the Rocky Mountains, for the purpose of
ascertaining the most southerly pass across to the
Pacific, within the British territory; and, 3, to report on the
natural features and general capabilities of the country, and
construct a map of the routes. The expedition sailed on
the 9th of May, 1857, and having arrived safely at New York,
proceeded to Fort William on Lake Superior, and thence to
Lake Winnipeg. The

The great project of communication by a ship-channel between
the Atlantic and Pacific has led to the investigation of routes
across the narrow Isthmus of Panama by different exploring
parties, but no route has yet been discovered which will
admit of a ship-channel being formed without locks or tunnels.

In South America, not long after the important journeys
of Spix and Martius, three European travellers crossed the whole
breadth of this continent, from the Pacific to the Atlantic,
descending the Amazonas, which was first explored by the
British expeditions of eighteen hundred and sixteen,
under Captain H. L. P. C. R.N., in 1828; Dr. Poppig, in 1831; and
Lieu-t. Smith, R.N., in 1834. Of these travellers Poppig added most to our
geographical knowledge. He went first to Chili, where he
spent two years; and then to Archangel, on the
North-West Passage, where he
sailed to Lima, whence he ascended the high table-land of
Pasco, and descended thence by the eastern declivity of the
Andes to the valley of the Huancu or Huallaga, where he
remained nearly two years, during which time he collected a
great deal of information respecting the climate, productions, and
gography of that country. From the Huallaga he passed
down the river Maranon, and thence returned to Europe,
after five years (1827 to 1832) of wandering in the wilds of the
New World, laden with 17,000 specimens of dried
plants, some hundreds of insects, many plants before
unknown, 3,000 descriptions of plants, and many sketches.
His work is a most valuable addition to our knowledge of
South America.

Nearly simultaneously, namely from 1836 to 1832, an-
other extensive journey was accomplished by Alcide d'Orc-
higny, who travelled through the Banda Oriental, Patagonia,
La Plata, Chili, Peru, and Bolivia, and published a very full
account with many illustrations.

More important than the results of the great Surveying Expeditions of the Adventure and Beagle, 1825 to 1836,
commanded by captains King, Stokes, and Fitzroy. The
coast-surveys of this expedition were very extensive: in
addition to which it brought home a greater mass of accurate
geographical information than any of the former
voyages of Cook and Flinders. Very valuable collections in
all departments of natural history were made by Charles
Darwin, the naturalist of the expedition.

During the years 1836 to 1844 Sir Robert Schomburgk
explored British Guyana and the country to the west as far as
E
the Orinoco and Casiguané. In reaching the Upper Orinoco he was enabled to connect his observations with those of Humboldt; and thus the completed series of French points of equal terrestrial determination, along a line extending from the Atlantic to the Pacific. One of the most interesting of his discoveries is that of the water-line named Victoria Regia, the most beautiful specimen of the flora of the western rivers, which has successfully been brought to Europe, and has been an object of admiration during several years.

In the same region, and extending over the whole of Venezuela, Colonel Geddes, by order of the government of that country, completed surveys which were embodied in a valuable work and atlas, executed at Paris.

Prince Adalbert of Prussia has explored the Xingu and some other rivers and regions in the lower basin of the Amazon, and visited by any explored.

In the southern portion of the continent some interesting observations were made by Mr. Bentland in the elevated regions of the Titicaca Lake in 1827 and 1838. According to these observations the heights of the Sora and Illimani, situated to the east of the lake, were long given out to be greater than that of Chimborazo, and the highest peaks of South America, but it has since been found that the trigonometrical surveys of M. Pissis, a French engineer, that the alleged elevation of Illimani was about 300 feet too high, and Mr. Bentland's, on recalculating his observations, admitted this error, and found that the elevation of Sora had even been assumed by him 4000 feet too high.

W. Bollast and G. Smith, who since 1826 have been residing for a considerable time in the province of Tampaca, Peru, have made us acquainted with a very remarkable region of South America, a full account of which was published in 1834 by Mr. Bollast. In it the silver mines of the region along the coast, the Desert of Atacama in its deposits of nitrate of soda, salt, and other saline substances, and the Andes, have been well described. Mount Lirima, the highest peak of that portion of the Andes, is estimated at 29,000 feet, which, if correct, would place it above all other American mountains.

The provinces of La Plata have been well described by Sir Woodbine Parish, in a work published in 1839, of which a second edition, much enlarged, appeared early in 1839; and the French traveller Castélan, accompanied by the English naturalist Weddell, has since explored the little-known regions between the upper course of the Plata and the Peru-Bolivian table-land.

In the survey of the American coast, Sir Francis Bissett, Baron, in a behalf in the House of Commons, thus stated their progress in 1846:—'From the equator to Cape Horn, and from thence round to the river Plata, on the eastern side of America, all that is immediately wanted has been already accomplished, and the survey of Cove of Edinburgh.'

"Some parts of the great empire of Brazil we owe to the labours of Baron de Boussin and of other French officers; but there is much yet to be done on that coast between the Plata and the Amazon rivers, and again along Guayana and Venezeula up to the mouth of the Orinoco.

"The shores of the mainland between Trinidad Island and the Gulf of Mexico have been charted and published by the Admiralty; but many of the West India Islands are still wanting to complete a wholesome knowledge of those seas.

"The United States are carrying on an elaborate survey of their own coasts, and to the northward of them; a part of the Bay of Fundy has been done by ourselves, as well as all the shores of Nova Scotia, Canada, and Newfoundland; and if these surveys are finished, we shall only want to complete the eastern coast of America, those of Labrador, and of Hudson's Bay, which, being in our possession, ought to appear on our charts with some degree of truth."

Since 1845, Captain Kellett, in H.M.S. Herald, has continued the western coasts from the equator northward, along Central America, Mexico, part of California, and other regions, and has thus completed the entire western coast-line of America. The Americans advance steadily with the work of their charts.

Since the publication of the American armies many political changes have taken place in the governments of North and South America. The present names of the various states, with the area, population, and capital town of each, are stated in the following table—which however some of the figures are only approximations.
ANACNE

27

ANC

ANASTHETICS. [Materia Medica, S. 2.]

ANAPA, a sea-port town and fortress of Russian Cir-
ca, situated on the eastern shore of the Black Sea, in 44°
30' N. lat., 37° 16' E. long., 30 miles N. from the harbour
of Sevastopol, and about 30 miles S.E. from the mouth
of the Kaban; population, exclusive of the garrison, about
300. It was founded by the Turks in 1784, to protect
the Tartar subjects on the left bank of the Kaban, as also
to keep up their depredations on the Cossacks. It is the
principal town of the beach, which is 16" long., and 16"
wide, and 5 miles wide. It is the principal town of the
lands which are occupied by the Russians. There is no
harbour, but only a broad roadstead at Anapa. The imports
are cotton and woolen stuffs, rice, tamales, flour, salt, and
the exports are ox, buffalo, and cow hides; hare skins, furs,
tallow, w.c.

The fortress of Anapa is built on a projecting crag, the
most north-western extremity of the Caucasian Mountains.
The surface is smooth and slopes down in an extended plain
on the north and east towards the Kuban. The walls
which the sea are 425 yards long, and the entire circum-
ference exceeds 2 miles. To the south-west the walls are
built upon a calcareous rock, which rises 65 yards perpendi-
cularly. It was never captured, and which, on the side of
the northern side of the town, the white cliffs that line its
shore subsides. Some bastions and a ditch defend the for-
teness on the side of the plain. During the Turkish pos-
session the place, about one mile square, was in part
occupied by the fortifications and in part occupied by 200 shops,
coffee-houses, and cabins built of wood, hedges, and mud.
It was ill-built, irregularly laid out, and had a very turbulent
population; but it is said to have improved in every respect
since its capture.

A body of 8000 Russian troops was an unsuccessful
attempt to take Anapa in 1790; the next year it was
attacked by General Gudovich, though defended by
16,000 Turks and 16,000 mountaineers. It was soon after
reduced by Boccardo and Piedicimeno, and was taken in 1803,
and in 1809. It was again restored to Turkey by the treaty
of Bakharest. The Russians finally took Anapa, June 23,
1856, after an obstinate defence, and held it till the Russian
War 1854-5, when they were obliged to evacuate it; but they
have held it from that time.

ANAMERTA. [Materia Medica, S. 2.]

ANAS, the Duck, a genus of birds under which Linnéus
included a great number of species now separated into
several genera by recent naturalists. [Ducks.]

ANASTATIC, a genus of plants belonging to the natural
order Crucifera. One species, A: hierochuntina, the roes of Jericho. [Jeseco, Ross or.]

ANATHERUM, a genus of Grasses, belonging to the
family of the Gramineae: its species is the Anerum of the French, and the Huus of
the Flinders. Its fragrant roots are employed in making tatties,
cups for palumpanis, &c. It is administered medicinally,
and has stimulating and diaphoretic qualities. A. ranunculas
is also, as a source of the vegetable oil it contains, called Ginger-
lin, or Koobel.

ANCON-SALINA, a deep and extensive inlet on the
western coast of South America, situated between 50° 30'
and 25° 30' S. lat. and 37° 20' to 73° 40' W. long., is remarkable
for bordering the southern extremity of the Andes. The
Sonic enters into Smyth Sound, which separates the
Alsea Archipelago from the continent of America. It
penetrates by a very winding channel (40 miles long, and
from 5 to 10 miles wide) through the islands of the
Sonic, and expands at its eastern extremity into a large
sheet of water, called Kirke Water, which is 20 miles long
and 10 miles wide. From the channel several arms branch
north and south. The most western, which is called the
Gulf of the Pacific, is about 20 miles long. It is entered by
a narrow strait, the passage between which is nearly
Christmas this arm on the west is considered to be the southern
extremity of the Andes. From Kirke Water two deep

tides branch off. One of these, called Last Hope's Inlet,
extends northward and then north-westward, with a
distance of about 30 miles; the other, which
 terminates not far from the northern extremity of the
Fund of the Mountains, from which it is separated by a
high snow-capped range. The other, called Obstruction
Sound, runs southward for about 70 miles, and is from 8 to
6 miles wide. The western shores, both of Obstruction
Sound and of Last Hope's Inlet, are lined with high moun-
tains, in some places covered with perpetual snow, but
the greater part of their eastern shores, as well as the eastern
shores of Kirke Water, consists of level ground, which ex-

tends some distance inland, where only a few low hills and
some rising ground appear. It is therefore evident that the
Ancon-San-Dal is cut through the whole range of the moun-
tains, and terminate near the gulf of the Patagonia.

(Surviving Voyages of the Adventure and Beagle.)

ANCEON, a delegation or province in the States of the
Church, is bounded N. and W. by the province of Urbino,
and E. and S. by the Adriatic Sea. Its greatest length is about 38 miles, and the breadth is
about 16 miles. The area is 408 square miles, and the
population in 1843 numbered 166,114. The surface is
traversed by numerous offshoots of the Apennines, which
are separated by fertile valleys. If the rivers which are
small, the principal are—the Misa, the lower part of
which is in the province of Urbino-o-Pesar, and enters the
sea at Signigalia; the Eino, which has its source in the
province of Macerata; and the Musone, which forms the
boundary between the provinces. The whole area of the province is 280 (940,424) acres,
106,016 acres are under cultivation; 85,780 acres are covered
with plantations and copses, and the rest consist of olive-groves,
farms, meadows, natural pastures, etc., the whole
amount of absolutely barren land is only 296 acres.
The chief agricultural products are wheat, maize, hemp, hay,
tobacco, wine, oil, and beans. Some silk is also produced.
Sheep and hogs are reared in great numbers. There are
also many horned cattle.

The province comprises the northern part of ancient
Pisenum, with a small portion of Umbria; these two
provinces were separated by the Eelsis, now the Eino, which
river also formed the boundary between the Galli Senones
and Pisenum, and was therefore the northern limit of Italy
on the side of the Adriatic until this was afterwards
extended to the Rubicon. The province contains only a part
of the old Marches of Ancona, which formerly extended
from the duchy of Urbino on the north, to the Marches of
Fermo on the south, and to the Abruzzi on the east; other
towns which require notice here are Iesi and Osimo.

Iesi, 16 miles W. by S. from Ancona, near the left bank
of the Eino, and about 10 miles from its mouth, occupies
the site of the ancient Umbrian town Eelsis or Eelium,
which became a Roman colony, and was famous for its
cheese. It gives title to a bishop, and is a walled town
of considerable size, with a cathedral, five parish churches,
and several convents. Silk and woolen hosiery are manufactured.

Osimo, the ancient Auussinum, and a bishop's see, is
situated on a high hill in the midst of a beautiful and fertile
country, 8 miles S. from Ancona, on the road to Loreto, in 49° 31' 36" N. lat., 13° 27' 30" E. long.: population about 7000. It
is a healthy and well built place, with a cathedral dedicated

to St. Tecle; a town-house containing a museum of ancient
statues and inscriptions found in the neighborhood; a hand-
some episcopal palace; and several churches which contain
some good paintings. Auussinum, from the strength of its
position, was a place of importance in ancient times. The
Roman censors had walls built round it n.o. 174, and it
came a Roman colony n.o. 157.

In the great civil war the partisans of Pumpeius setded the
town n.o. 49, but the inhabitants refused to change
their allegiance to Caesars. Ancon became the capital of
Pisenum, of which it was always one of the strongholds.
Belisarius took it from the Goths after a long siege, during which it narrowly escaped
destruction. Under the Byzantine empire, Auussinum was one of the
of the empire in the Elesian Archipelago.

ANCUD, THE GULF OF, extends between the mainlands
of South America and the island of Chiloe, from 41° 30'
to 43° 30' S. lat., and from 72° 40' to 73° 80' W. long. It
comprises the narrow winding strait of the Narrows of Chaco, which are of considerable depth, but at
some places hardly a mile wide. On the south of the
island of Chiloe it is connected with the Pacific by the wide
opening which occurs between the Chonos Archipelago and the
island of Chiloe, which is about 20 miles long, and about 150 miles wide (including its expansion towards the north,
which is called Reloncavi Sound), and at an average 60 miles
wide. Its shores are everywhere high, and formed by rocks.
ANG

88

In the middle of the gulf, between 42° 10' and 43° 50', are a great number of high rocky islands and islets. The southern part of the Bay of Arcos is in some maps named the Gulf of Covarrubias. (Surveying Voyages of the Adventure and Beagle)

ANGLESEY, HENRY WILLIAM PAGET, MARQUIS OF, eldest son of Henry, first Earl of Uxbridge, was born May 17, 1792, and educated at Charterhouse School and Christchurch, Oxford; and entered Parliament as member for the Caernarvon boroughs in 1790. His predilection was however for a military life, and it found free scope at the outbreak of the revolutionary war in 1793, when he eagerly set to work to help his father’s cause. He joined at first the Staffordshire Volunteers, but which was admitted into the establishment as the 80th foot. Of this regiment he was appointed lieutenant-colonel on its having made up its complement of 1000 men. At the same time he received a commission to the rank of major in Sir Henry Erskine’s regiment of the Guards, and on being transferred to the command of a cavalry regiment, and commenced the career which at no distant day caused him to be regarded as the first cavalry officer in the service. As commander of the cavalry he accompanied the Duke of York into Holland, and although in no respect distinguished himself, he had few opportunities of acquiring distinction, but in the general attack Lord Paget succeeded in defeating a much superior body of the enemy’s cavalry; and in the retreat, where he occupied the rear, he gained a signal triumph over a much larger force advancing to the rear. In 1806, he was appointed to the command of the cavalry of the 3rd division, which he maintained at home diligently occupied in training the regiment of which he was colonel, and in carrying out the system of cavalry evolutions which he had introduced, until near the end of 1808, when, having previously been made major-general, he was sent into Spain with two brigades of cavalry to join the army of Sir John Moore. In forming this junction General Paget was perfectly successful, and on the road he succeeded in cutting off a party of French posted at Rueda—three thousand men altogether. After that battle he attacked the French in Spain. On joining Sir John Moore the cavalry under Lord Paget was pushed forward, and on the same day, December 20, came up with a superior body of French cavalry, and defeated it, taking above 120 prisoners, including two lieutenant-colonels. These victories gave the English cavalry an amount of confidence in themselves and their commander, which in the subsequent retreat was of the utmost value. During the retreat Lord Paget with his cavalry formed the rearguard of the French infantry and artillery, and on quitting Benevento he received intelligence that the enemy had arrived, and that their cavalry were crossing the Esla. Lord Paget hastened to the ford, and directed the 10th Hussars under General Stewart to charge the Imperial Guard, who had crossed. The French were driven back with a considerable loss in killed, wounded, and prisoners, among the latter being General Lefebvre Desnoeux, commander of the Imperial Guard. At the battle of Corunna Lord Paget had the command of the reserve, and his charge in support of the right wing, which was menaced by a far superior force, decided the fortune of the day.

Lord Paget returned to England in 1809, and did not again serve abroad during the Peninsular war. In 1810 he was divorced from his first wife, by whom he had had eight children. Soon after the divorce Lady Paget married the Duke of Argyll, and Lord Paget married Lady Cowley, who had just been divorced from Lord Cowley. In 1812 he succeeded, by the death of his father, to the title of Earl of Uxbridge.

In the early part of 1815 the Earl of Uxbridge commanded the troops collected in London for the suppression of the corn-law riots; but a more important service soon devolved upon him. When Napoleon escaped from Elba, and startled Europe by his re-appearance on the imperial crown, the armies of the allied sovereigns were at once set in motion against him. The Earl of Uxbridge was appointed commander of the cavalry of the English army, and his management of this branch of service excited general admiration. At the battle of Waterloo he fell mortally wounded; but as his command was conspicuous amidst the almost unspeakable gallantry of which that field was the theatre. It was the final charge of the heavy brigade, led by the earl, that destroyed the famous French Guard, and to that the hopes of the emperor. Almost at the close of the battle a shot struck the earl on the knee, and it was found necessary to amputate his leg. The limb was buried in a garden by the field of battle, and some sentimental Belgian admirers erected a monument in commemorating the circumstance, which is always one of the objects shown to visitors to Waterloo. The service rendered by the earl at Waterloo was generally recognized and duly rewarded. Immediately the dispatches of the commanders-in-chief were received in the name of his majesty, the dignity of Marquis of Anglesey, and nominated a Knight Grand Cross of the Order of the Bath; while he received from the emperors of Austria and Russia, and other European sovereigns, corresponding knighthoods.

In 1819 he was elected to succeed his father as minister of the home department, and continued to hold the full rank of general; at the coronation of George IV. he held the office of Lord High Steward of England; and in 1820 received the sinecure offices of Captain of Cowes Castle.

When Canning became prime minister in April 1827, the Marquis of Anglesey formed one of his cabinet, having succeeded the Duke of Wellington as Master-General of the Ordnance; but this office he resigned in the following spring to become, under the ministry of the Duke of Wellington, Lord Lieutenant of Ireland. The duties of this important station the marquis addressed himself with characteristic energy, and by his zeal, impartiality, and ardent temperament, won a remarkable share of popularity. But his earlom estran his discretion. He had already in conversation expressed the opinion that the duty of carrying the peace of the kingdom would be better performed by a nobleman than by a soldier, and found to be inconvenient; and when, in December 1826, he wrote a letter to the Roman Catholic primates directly favorable to Roman Catholic emancipation, he was at once recalled. The day of his departure from Ireland the works in process of construction there were opened, business was suspended, and his embarkation was attended by large numbers of all classes of the citizens. In the House of Lords the marquis was a warm advocate of the measure which his letter of March 1827, written in reply to Canning’s letter, and addressed as the cause of the ministerial break-up, also quitted office. Of the thorough honesty of purpose of the marquis’s administration of his vice-regal functions, after the temporary triumphs against Napoleon, he had been the most conspicuous, and nothing but the most extraordinary public spirit can have induced him to surrender any high order of statesmanship there can be no pretension raised. The institution by which his tenure of office is most likely to be remembered is the Irish Board of Education, which was originated and carefully fostered by him, and for whose establishment he succeeded the greatest benefits conferred on Ireland in recent years.

From this time the marquis took little part in public affairs until the formation of the administration of Lord John Russell in July, 1846, when he again became MasterGeneral of the Ordnance; the duties of which office he sedulously performed till February, 1852, when the Russell ministry was replaced by that of Lord Derby. He was made colonel of the Horse-Guards in 1842, and was advanced to the dignity of field-marshall in 1845. He died full of years and honours April 29, 1854. By his first wife the Marquis of Anglesey had issue two sons and six daughters; by his second wife he had six sons and four daughters. He was succeeded in his title, and as lord-lieutenant of Anglesey, by his eldest son, the present marquis.

ANGOULÉME, DUC AND DUCHESSE D', Louis Antoine de Bourbon, Duc d'Angouléme, and afterwards Dauphin of France, the son of the Comte d'Artois (afterwards king by the marriage-in-chief of the Austrian imperial archduchess, X.), was born at Versailles on the 6th of August, 1775, and died at Götitz on the 3rd of June, 1844. He was fourteen years of age when the revolution broke out. The Comte d'Artois in order to protect by his absence those concessions which he had made to the revolutionists, offered to marry one of his two sons followed him to Turin, the court of their grandfather, where for some time they devoted themselves to the military sciences. In 1792 the young duke received a commission in Germany, but attained no distinction. The ill success of this campaign induced him to return to a state
In the north, on which side it is defended by a massive wall flanked with numerous towers. The towers are remarkable for the gigantic cisterns formed by huge blocks of red sandstone let into the masonry. The walls, towers, and churches are in good preservation; so much so, that at a distance the city does not seem deserted. Besides the buildings the public buildings display much elegance and architectural beauty, and the fritework of the arches is very rich. Some of the churches are decorated with rude wall-paintings representing scriptural and legendary subjects. There are a few Turkish houses, but some are Turkish. The private houses of Ann are supposed to have been of an humble description, as none of them are left standing, and the whole area on which they stood is covered merely with mounds of loose stones. The city continued to be inhabited till a.d. 1818, when its ruin was completed by an earthquake. (Wilbrahim’s Travels in the Trans-Caucasian Provinces of Russia.)

ANTHOPODES, the name given to Human Fossil Remains. At one time it was thought that human remains were often found fossilised, the investigations of modern anatomists have shown that in most of these cases the supposition is false. Daubenton first demonstrated that some bones which had long been regarded in Paris as human, were of the domestic fowl; and the same tribe of beings. The researches of Cuvier gave a clue by which all cases might be tested, and most of the earlier instances brought forward have been referred to their correct types. Human fossil bones have, however, been discovered in the
Belgian bone-caverns, with bears, rodents, &c., and are figured by Dr. Schmerling, in his interesting work on the bones found in a cavern near Liège.

Dr. Buckland ('Bridgewater Treatise') remarks that frequent discoveries have been made of human bones and rude works of art in natural caverns, sometimes inclosed in stalactite, at other times in beds of earthy materials, which are interspersed with bones of extinct species of quadrupeds.

These cases, he thinks, may be explained by the common practice of mankind in all ages to bury their dead in such caverns. "The practice of burying in caverns continues," says Dr. Buckland, "that many caverns contained the bones of extinct species of other animals, dispersed through the same soil in which human bodies may, at any subsequent period, have been buried, affords no proof of the time with which they were interred. Many of these caverns have been inhabited by savage tribes, who, for convenience of occupation, have repeatedly disturbed portions of soil in which their predecessors may have been buried. Such disturbances will explain the occasional admixture of fragments of human skeletons and the bones of modern quadrupeds with those of extinct species introduced at more early periods and by natural causes. Several accounts have been published within the last few years of human remains discovered by miners of France and Belgium in parts of the province of Liège, which are described as being of the same antiquity with the bones of hyaenas and other extinct quadrupeds that accompany them. Most of these may probably admit of explanation by reference to the causes just enumerated. In some cases, however, it is certain that the caverns, in which form bones of elephants, rivers, or which are subject to occasional inundations, another cause of the admixture of human bones with the remains of animals of more ancient date may be found in the movements occasioned by running water."

The same learned author observes that the most remarkable and only recorded case of human skeletons imbedded in a solid limestone rock is that on the shore of Guadaloupe, adding that there is, however, no reason to consider these bones as of any antiquity, as the circumstance which occurs is of very recent formation, and is composed of agglutinated fragments of shells and corals which inhabit the adjacent water. Such kind of stone is frequently formed in a few years from sand-banks composed of similar materials, on the shores of tropical seas."

antimony. [Chemistry, S. 1.]

ANTOMMARCI, FRANCESCO, a surgeon of some repute as an anatomist, but more likely to be remembered in the year 1836, when on the appointment to Napoleon, at St. Helena, he was the first to be the architect of Antommarchi's versai; it was affirmed that he had unlawfully assumed the title of professor, and that nobody had been able to find two works that he had published—the one a treatise on the cholera, the other a commentary on the subject of phrenology, in their spineless adored, so far as to throw a suspicion upon the identity of the cast considered with regard to the material. 'Your cast,' they said to him, 'is of a fine plaster; it is white and pure, as such is only to be seen at London, where being formed of it, you could not have found any such at St. Helena.' Wearing with all these vexations, Antommarchi about 1836 took the desperate step of emigrating, in order to practise homoeopathically at New Orleans, and afterwards at Havanna." He died at St. Antonio in Cuba, about 1844.

APPYLOCIC ACID. [Chemistry, S. 1.]

APPPEY, CHARLES JAMES, a writer on sporting subjects of considerable reputation, better known by the pen-name of "Damoiselle Callot," he was the second son of Thomas Apperley, a Welsh country gentleman, and was born in his father's seat of Pilgrownen, in Denbighshire, in the year 1777. At Rugby school he acquired some knowledge of the classical languages, and much more of the sports of the field. In 1801 he married the daughter of William Wynne, Esq., and in 1804 he took up his residence at Bilston Hall, once the county seat of Addison, in Warwickshire. Here he devoted himself so entirely to the chase that for some years his only pursuit was that of a fox-hunter. He often rode thirty or forty miles in a day, without much regard to the expenses of the sport by disposing of hunters, after he had ridden them for some time, to those of his friends whose knowledge of the horse was not so intimate as his, and who therefore could not estimate the value of such a purchase of an unridden animal. In 1821 he removed into Hampshire, and commenced farming on a large scale; and in the same year he began to write for the press. His contributions to the 'Sporting Magazine,' especially his Hunting Tours, and his elegant descriptions of various places of interest. His style was that of a well-bred gentleman; and the circulation of the work was doubled in two years; and Mr. Pitman, the proprietor of the magazine, not only remunerated him handsomely, but also paid the expenses of his tours, and kept for him a stud of horses, which formed the most splendid collection of foals that ever was exhibited. After his death, owing to the circumstances mentioned above, the result of which was that, to avoid a prison at home, Nimrod was compelled to take up his residence in France. In
APT

AQUARIUM, a contraction for *Aquaria vivarium*, a term applied to arrangements of living aquatic animals and plants inhabiting either fresh or salt water. Although it has been known from the earliest times that animals living in water may be kept in glass vessels for exhibition by the daily supply of fresh-water, the discovery and adoption of modern chemistry have pointed out how animals may be kept living in only limited quantities of water which never demand renewing. The possibility of accomplishing this depends on the animal which can thus be kept in chemically pure water, and vegetable kingdoms. The one set of these beings are engaged in giving off what the other requires, and in taking up what the other rejects. It is thus that the carbonic acid which is thrown off from the tissues of animals is taken up by water plants, and oxygen is supplied from the atmosphere; whilst the plant gives off oxygen gas, and supplies the atmosphere with this element of its composition which is necessary to the life of animals. The relations which are thus found to exist on the large scale of the whole surface of the earth, are found also to occur in a jar of water. If an animal is placed in pure water it quickly exhausts the oxygen it contains, and gives out into it carbonic acid gas; the consequence is, that it dies. But if we place with the animal some plants which live in water, and which in the carbonic acid given out by the animal will be taken up by the plant, and that the plant will give out oxygen in its place. Thus the water becomes cleared of its injurious compound, and the needed element, oxygen, is supplied. Such an arrangement is on a small scale to be considered. The first experiments were made with fresh-water by Mr. N. B. Ward, and one of the earliest accounts of such an arrangement was given by Mr. Warington, chemist to the Apothecaries' Company. The latter found out, however, that it was not necessary to have a living specimen, as it has been exhibited in the gardens of the Zoological Society, Regent's Park. Of all birds at present known the Aepyornis appears to have the wings the most reduced to their simplest elements. Its general form is that of the Penguin, and in so far it is seldom quite so big as our common goose. The beak is very long and slender, marked on each side with a longitudinal groove, and covered with a membrane at its base. It differs from other birds in the completeness of its diaphragm, and in the absence of abdominal air-cells. The bones are not hollow, as is mostly the case in birds; the sternum is very small, and the ribs are extraordinarily broad; the feathers have no accessory plumes, and their shafts are prolonged beyond the back; the feet have a short and elevated hind-toe, of which the claw alone is externally visible. The native name of this bird is Kiwai-Kiwi, given it on account of its peculiar cry. It is a nocturnal bird, and preys on mallards, insects, and worms. Whilst at rest it has the singular habit of resting upon the tip of its bill, which is its only characteristic position.

Whilst at rest it has the singular habit of resting upon the tip of its bill, which is its only characteristic position.

APTENODYTES. [Penguins.]

APTERYX, a genus of Struthious Birds, inhabiting Australia and the islands of New Zealand. It was first described by Dr. Shaw, who regarded it as an extinct form of bird. It evidently belongs to a group of birds that were destined to be on the earth, only as long as they were free from the attacks of carnivorous enemies endowed with greater powers of detection than themselves. Members of wingsless birds, not belonging to the Struthious division, as the Dodo and Solitaire, seem already to have become extinct; whilst the smaller species of the *Dinornis* are suffering in like manner. The Aepyornis is not however extinct, as many stuffed specimens are in the British Museum, and a living specimen has been exhibited in the gardens of the Zoological Society, Regent's Park. Of all birds at present known the Aepyornis appears to have the wings the most reduced to their simplest elements. Its general form is that of the Penguin, and in so far it is seldom quite so big as our common goose. The beak is very long and slender, marked on each side with a longitudinal groove, and covered with a membrane at its base. It differs from other birds in the completeness of its diaphragm, and in the absence of abdominal air-cells. The bones are not hollow, as is mostly the case in birds; the sternum is very small, and the ribs are extraordinarily broad; the feathers have no accessory plumes, and their shafts are prolonged beyond the back; the feet have a short and elevated hind-toe, of which the claw alone is externally visible. The native name of this bird is Kiwai-Kiwi, given it on account of its peculiar cry. It is a nocturnal bird, and preys on mallards, insects, and worms. Whilst at rest it has the singular habit of resting upon the tip of its bill, which is its only characteristic position.
of this paradeogram are bounded by reservoirs of plate-glass, each being about 6 feet in length and 2 feet 6 inches in depth. These are held in position by a projecting base resembling the ground, so that each division presents as it were a submarine picture 'on the line,' and may be approached so closely that the minutest animals not microscopic, may be watched with the most perfect success, under circumstances which in reality are of nature.

The whole of these tanks are supplied with gravel, sand, rocks, and sea-weed, so as to imitate the rock-pools left on the seashore by a receding tide, which indeed they may be said to represent; for they have the greatest advantage to the observer that lies in looking vertically into a cavity in which the light becomes less and less in proportion to the depth, he has here the means of examining each animal in its turn, under an effect which is not only most delightful in itself, but this being seen in section through an artificially transparent wall, affords the best possible position for investigating the structure and functions of the living beings contained in it.

The tanks contain fresh-water animals and marine animals. The fresh-water tanks present all the more common species of British Fishes, as the Pike, Tench, Perch, Roach, Rudd, Carp, Eel, Stickleback, Minnow, Gudgeon, etc. Some of the larger forms of fresh-water Crucates, as the Crawlifish, have also been introduced. With the Stickleback a large variety of the fresh-water Mollusca, belonging to the genera Lymnaea, Planorbis, Anodonta, Unio, &c. These tanks have been occupied since Christmas, 1852, with scarcely any loss.

Amongst the Radiate Animals none are more remarkable for their size and beauty than the Scutarian Zoophytes and the Polyzoa are also there, but their animal inhabitants are too minute to be seen with the naked eye. Specimens of the Echinoderma, including several forms of Star-Fishes (Asteroidea), the star Limpets, Sea-Snails, etc. of an equal size, are also represented. The other rare forms of this class of animals have been from time to time introduced.

As was to be expected, the Mollusca thrive. In the sea they play the same part as in the fresh-water : they are the scavengers of the ocean. The Pinna, the Oyster, the Pecten, the Cockle, amongst bivalves; and the Whelk, the Periwinkle, with many other molluscs, have demonstrated how large a field of observation is in store for those who study the Mollusca, as well as the forms of the animal kingdom. The Nudibranchiate Mollusca, those forms and colours are only known to us through the great work of Alder and Hancock, have been successfully kept alive; whilst the red leaves of the species of Rhodophyta have been kept in exciting health for several years. The eggs of Mollusca have lived, and complete the evidence that this great group of animals may he watched in their living habits as easily as their shells may be examined in a cabinet.

Most of the Articulata have been represented in these tanks by species of Lobster, Crab, Shrimp, and Prawn. Though many of these are inhabitants of the deep sea, and only reward the labour of the dredger, yet they live perfectly well in the shallow lodges provided for them by the Zoological Society. These facts demonstrate that amongst the Invertebrate tribes there are none whose habits may not be studied in the Aquarium.

With regard to fish it is found that those which live in streams thrive best in the Aquarium. The Cork-Wing (Cernbubrus Cornucibix), the Fifteen-spined Stickleback, the Long-spined Cottus, two species of Benny, the Goby, the Grey Mullet, and the Flat Fish have lived remarkably well.

ARABGIR, a town of Asia Minor, in the pashalik of Sivas, is situated on an elevated plateau between the Gil-Dagh and Sari-Chi-Chak branches of the Anti-Taurus [Anatolia]; at a distance of 16 miles N.W. from the junction of the Kara-Sin and Murad-Su, on the caravan route from Aleppo to Trabzon, from which places respectively it is distant 270 and 198 miles. It is built amidst a forest of fruit-trees, among which the White Mulberry is most common. The water of the mulberry is sweet, fresh, or brackish, according as it be brandy, or it is made into a sweetmeat called Petmes, which is common all through Armenia. The soil in the neighbour-

hood where it is free from rocks yields fine crops of wheat. The snow begins to fall in December, and the place lies in a snow climate. The town contains 4800 Turkish and 1260 Armenians.

A few years ago the Armenian population had 1000 hand-locks at work, weaving cotton goods from British yarn. This industry and the caravan trade rendered Aragib a thriving place, but the land is now so barren, iron ore is abundant; and near the spot where the above-named river meets and form the Euphrates, are the lead and copper-mines of Kaban-Maden. (Royal Geog. Soc.)

ARAGO, FRANÇOIS JEAN DOMINIQUE, was born in the commune of Estagel, near Perpignan, province of Rousillon (now the department of the Eastern Pyrenees), on the 20th of February, 1786. His father, a licentiate in law, supported his numerous family on the income derived from a small landed property, acquired the rudiments of reading, writing, and vocal music at the primary school of his native place, and in private lessons at home. He became an eager reader, and at an early age conceived a taste for scientific life, and nourished by the continual passing of troops on the march to or from the frontiers of Spain. When but seven years old he attacked with a lance the leader of a few Spanish troopers who had ridden by mistake into the village after a battle, and was only saved from injury by a lucky chance. At the age of thirteen, all he thought of was study and study—six hours a day, and four hours a night. He had been appointed Treasurer of the Mint in Perpignan, the family removed to that town, where he was entered as a cadet at the Musée de l'Armée, and pursuing his literary studies, made himself acquainted with the celebrated author of his native country. But walking one day on the ramparts, a little incident occurred that confirmed his military inclinations. Seeing a youthful officer directing the repairs of the fortifications, Arago was surprised to see the man of twelve,

though he was not exactly a washerman, be familiarised himself with the writings of Legendre, Lacroix, and Garnier. His real master, to quote a passage from his autobiography, was a cover of Garnier's 'Treatise of Topography;' and he soon mastered the elements of this branch of study stood alone, at the time, as a branch of study, and was answered—By study at the Polytechnic School, which was open to those who had passed a preliminary examination. From that time Arago, then in his twelfth year, betook himself to the study of mathematics and geometry, not in elementary manuals, but in the original works of the best authors, and mastered their contents with characteristic energy. He soon outstripped the whole who taught mathematics, and was only surprised by the unexpected testimony of a neighbouring proprietor, who was a military man, be familiarised himself with the writings of Legendre, Lacroix, and Garnier. His real master, to quote a passage from his autobiography, "was a cover of Garnier's 'Treatise of Topography;' and he soon mastered the elements of this branch of study

in eight months Arago was ready in the examinations, but the examiner having been detained by illness, a delay occurred, during which his friends sought to divert him from the pursuit he had chosen. He kept on, however, and studied the works of Euler and Laplace, and took lessons in fencing and dancing, having heard the story of these accomplishments from an officer of the name of Petmez. As he was examined by Monge at the University of Toulouse, and passed with high commendations first of his class. He repaired forthwith to Paris, and entered the Polytechnic School, after a few months, he was summoned hastily from an examination by Legendre as follows at that from Toulouse. In either case, his readiness and familiarity with the subjects required, overcame the prejudices of the examiner.

He was studying for the artillery branch of the service when, in 1804, he post of Secretary to the Observatory
at Paris, then under Bouvard's direction, having fallen vacant, he was persuaded, but with great reluctance on his part, to undertake the duties. The temporary appointment, as he thought it, effected an entire change in his pursuits, for he remained attached to the Observatory for the rest of his life. At the instance of Laplace he worked with Biot, who was assistant-observer, at experimental researches for determining the refractive power of different gases—an inquiry connected with the results of which formed the subject of a paper presented to the Academy and printed in their "Memoirs" for 1806. In the same year the two young men were appointed by the government to extend and complete the measurements of the arc of the meridian, at Beijing. It was found, under the superintendence of Delambre and Méchain, had been interrupted by the death of the latter. It was now to be extended from Barcelona to the Balearic Isles, and thence to Fontenay, by an immense triangle, the measurement of which had been thought impossible. The fatigues of this survey in a wild mountain region, exposed to heat, cold, and storm, were excessive. For six months Arago was stationed on an elevated peak in the Deserti de las Palmas, watching for the light on up on Ivis, which, owing to a defect in fixing the cross lines, was not discovered. On the summit of the fire square yards was all the ground he had for exercises; and two Carthusian monks, who, forgetting their vow of silence, used to ascend the mountain to converse with him in the twilight hours, the frequent journeys, in which, apart from the fierce heats, much risk was incurred owing to the hostile feeling between France and Spain, and from parties of brigands. On two occasions a notorious robber-chief intruded himself as a sightseer into the camp.

The geodetical union from the mainland to Ivica, and thence to Fontenay—an arc of parallel of one degree and a half in one triangle—was successfully accomplished. Biot had returned to Paris, when, in the summer of 1806, the first expedition on Mount Galazzo, for mapping the Swabian Alps, was sent under the command of Arago. For his advice, which demonstrated itself not only in the execution of the survey itself, but in the arrangement of the apparatus in the camp, and Arago was denounced as a spy. To escape the threatened violence, he obtained permission from the governor to appoint himself in the island of Bler. Having a safety-pass from the English Admiralty, he escaped in a half-decked boat to Algiers in July. In August he sailed for France in an Algerine frigate, and was in sight of the coast of Provence when the vessel was captured by a Spanish privateer, and carried into Roads. Here he was again exposed to great danger: the authorities, bitterly suspicious, subjected him to repeated examinations, and consigned him to the hulks at Palamos, where his sufferings from want of food were, as he tells us, aggravated by the sight of the Pyrenees, and the thought of his祖国. He would then be looking up at their peaks, anxious for her.

Being liberated on demand of the day, he sailed once more for France on September 25, and was off the port of Marseille when the cock crowed, caught by the nurse, was drafted away for the Mediterranean to the coast of Africa. Arago landed at Boogie, and having travelled to Algiers, found a new day in power, who would have sent him to the galley but for consular interference. Here he lingered, waiting for an opportunity to return home, until June, 1809, when he again sailed, and though chased by an English cruiser, landed at Marseille on the 2nd of July, with his manuscripts and instruments. For eleven months he had been tossed about amid hardships and privations, of all of which he has left an interesting account in his "L'Histoire de ma Jeunesse."

While yet in the lazaretto, he received a letter from Humboldt—the commencement of a lasting friendship with the illustrious Prussian. Tenderness attached to him; mother's first visit was to her at Pargimgan. She had mourned him as dead.

Arago hastened to Paris to communicate his observations to the Academy and the Bureau des Longitudes. Though let to his works in poverty, and exposed to the world's contempt and suspicion by his labors and misfortunes; and the death of Lalande having left a vacancy in the Academy, he was elected a member by 47 out of 80 votes on the 17th of September, and from that time honored with the usual presentation to the Emperor. Thereafter, he was admitted into a learned body; and his opposition to unworthy candidates brought him at times into collision with some of the most eminent of his colleagues. Before the close of 1809 he was appointed assistant-astronomer to the Observatory, and to succeed Monge in the chair of analytical mathematics at the Polytechnic School.

In 1811, taking up the researches in Mains, he read a paper to the Academy in which knowledge of the laws of light was greatly extended, and the changes described that take place in polarised rays on passing through different kinds of crystalline plates. The phenomena of colour, of intensity, of rotation, and of reflection, were examined, and by a new and original mode of effecting the experiments. One of the most interesting results was the discovery of the effect of an opaque medium, as the atmosphere when the sky is clouded; the polarised light varies with the height and position of the point with respect to the sun.
current. He proved moreover the best magnet to be a steel bar inclosed by a helix of copper-wire, to which we owe the discovery of the electro-magnet, and all that has since been accomplished thereby. Four years later other facts were also proved; and it was shown that not magnetism alone exert a powerful influence on the magnetic needle, particularly when in motion. Such metals appeared to become magnetic by mechanical motion—a phenomenon which has since been referred by Faraday to general laws of mechanical induction.

In 1829 Arago was chosen a member of the Bureau des Longitudes, and from 1834 till his death the \textquoteleft Annuaire', published by the board, contained a notice on some scientific subjects of general interest, as well as on others. \textquoteleft They were always to be republished,' says M. Combes, president of the academy, \textquoteleft with the same pleasure by men of science and by the ordinary reader. In them we find an admirable clearness, with an erudition as correct as it is extensive, and joined thereto the most rigorous accuracy in the statement of the phenomena, and the consequences which result from them.'

Arago won the position and honour he most prized in 1830, when on the death of Fourier he was elected perpetual secretary of the academy. And now the duty devolved upon him of writing those \textquoteleft d\oeuvres' of deceased members which are among the most interesting of his literary productions—graceful in style, and abundant in anecdote and illustration. They appeared to be written with a fluent pen; but it is this power, and only this, which implies expression of expression by real and repeated hard work of mind and hand. In the same year he was appointed director of the Observatory.

In 1834 Arago visited England a second time, and attended the meeting of the British Association at Edinburgh. He continued his scientific researches, among which are—the discovery of a neutral point in the polarisation of the atmosphere—determination of the neutral points of the magnetic needle at places widely apart, by observations carried on simultaneously with Kupffer at Kassel—and the suggestion of a decisive proof of the truth of the undulatory theory, which has since been demonstrated by Foucault—besides other points of photometry and astronomy.

The later years of Arago's life were passed amid much bodily suffering, when, with failing sight and afflicted with diabetes, he set himself to finish his incomplete papers. In the summer of 1853 he went, attended by his niece, to his native place, seeking relief in change of air; but the hope was disappointed: he returned to Paris and died on the 2nd of October, aged 67. He was buried in the cemetery of Père-la-Chaise, followed by a concelebration of 3000 persons to the grave, where Flourens pronounced the funeral oration.

Arago was a member of the Royal Society in 1818. In 1825 their Copley medal was awarded to him for his \textquoteleft discovery of the magnetic properties of substances not containing iron'; and their Rumford medal in 1850, for his \textquoteleft experimental investigations of polarised light.' The Royal Astronomical Society elected him one of their associates in 1822; he was also a member of some of the leading scientific societies on the continent. Arago was once married: his wife died in 1820, leaving two sons, who still survive. He had been accused of boarding up wealth, but he left no other fortune to his relatives than a name and reputation of which they may he justly proud. His entire works are easily accessible, as they have been collected and published in a series of octavo volumes in French and English. It is said that he has left a narrative of his later years, not less interesting than that to which reference has been made above, for publication when the fitting time shall arrive.

National vanity and an impassioned nature at times involved Arago in bitter controversies with other savants, in which he too often lost sight of truth and justice. It is certain also that he was occasionally tempted to sacrifice accuracy to effect. In politics he was an ardent republican, to which he was led by his devotion to the character of Deputies after the \textquoteleft Three Days' of July, 1830. By his eloquent advocacy the observatory of Paris was placed on its proper footing among the observatories of Europe, and the works of Laplace and Fermat were published at the national expense. His communications in favour of science. To his residence at Claro, the Italian philosopher, owed his return to Naples from a wearisome exile. In 1840 he became a member of the Council-General of the Seine; and in 1848 he was chosen into the Provisional Government, in which he discharged the functions of minister of war and marine. In bitterness of spirit he deplored the failure of the republic on witnessing the popular caprice. He refused to take the oath of allegiance after the coup-d'état of 1851, and justified his refusal in a memorable letter to the government, which elicited a concession alike gratifying to his conscience as a politician and his dignity as a philosopher. \textquoteleft A special exception,' so wrote the minister authorised by the Prince-President, \textquoteleft would be made in favor of a philosopher whose labours had rendered France renowned, and whose existence the government would be loth to sadden.'

ARAGUAUYA, one of the largest and most important rivers in the interior of Brazil, though up to the present time it is not much navigated, because the countries along its banks are unproductive, except at a few isolated places. It divides the province of Goyas, which lies east of it, from Mato Grosso, which extends west of its course. It rises in the Serra de Santa Martha, south of 18° S. lat. in a lake, and runs under the name of Cayapo about 160 miles, when it unites with the Rio Claro, which traverses the town of Villa Boa de the capital Goyas, and takes the name of Araguauy. Continuing in a northern direction to about 18° 30' S. lat., the river divides into two branches, which do not reunite until 9° 30'. The island which is thus formed is called Ilha de Santa Anna. It is more than 200 miles long, and at an average of 30 miles wide, so that it covers a surface of more than 6000 square miles. The western arm of the river preserves the name of Araguauy, whilst the eastern is called Furo. The latter is most used by the inhabitants of the town of Pará, and at a very few places on its shores the Portuguese settlers have formed establishments, whilst none exist on the western arm. In both arms some falls occur, but they are not considerable. After its arms have re-united, the river runs to 6° S. lat., where it joins the Tocantins. The whole course of the river probably does not fall much short of 1000 miles, and it receives the waters of several navigable tributaries south of 10° S. lat., among which the Vermelho and Crixia from the right, and the Rio das Mortes and San João from the left, are the largest. (Henderson's \textit{History of Brazil}).

ARANEIDE, the first family of the first order of the class Arachnidea. \textquoteleft\textit{Arachnida}.' They are also called \textit{Spinipeda}, from their peculiar habit of bearing long filamentous cords with which they form their nests and webs. It is to this family that the term \textit{Spider} is more especially applied; and scientifically it embraces all those creatures which are commonly called Spiders. All these are equipped under the old Linnaean name of Araneida. Externally this family is distinguished by the following characters:—The palpi resemble small feet without a claw at the tip, terminated at most in the females by a small hook, but in the males supporting various appendages, more or less complicated, connected with the function of reproduction in this family. The frontal claws are terminated by a moveable hook which curves downwardwards, and has on its under-side a little slit for the emission of a poisonous fluid which is secreted in a gland below the preceding joint. The maxillae are never more than two in number; the tongue is of a single piece, always external, and situated between the maxillae, and more or less square, triangular, or semicircular.

The thorax has upon it a V-like impression indicating the region of the head; it consists of a single piece, to which is attached behind a moveable and soft abdomen. This part of
the body is furnished with four or six nipples, fleshy at the tip, round or conical, united, placed close together, and point at the extremity with an immense number of minute nozzles for the discharge of silken threads, which are produced from matter formed in internal reservoirs. These are called Spiderers. The legs vary in length, but are composed of seven joints, of which the first two form the haunch, then the femur, the fourth and the fifth the tibia, and the sixth the tarsus. The last is ordinarily terminated by two claws, generally toothed beneath, and by a third smaller claw which is not toothed.

The most remarkable feature performed by the Spider is that of producing silken threads by means of the Spiderers above described and figured. From each one of the minute orifices of the Spiderer there exude as many little drops of a fluid, which becoming dry the moment it comes in contact with the air, forms so many delicate threads. Immediately after the filaments have passed out of the pores of the Spiderer they unite first together and then with those of the neighboring Spiderers to form a common thread; so that the thread of the spider, when it suspends itself from any object, is composed of an immense number of minute filaments, amounting even to many thousands, each of which is of such extreme tenacity that the naked eye cannot detect them till they are formed into a common thread. The Spiderers of the same spider differ in structure, and Lyonnets has shown that one set of Spiderers is employed in producing threads which are glistening, whilst another set produces threads which are smooth. This may be seen by throwing a little dust on a spider's web, such is that of a Spider, when it will be found that it adheres to the threads which are spirally disposed, but not to those that radiate from the centre to the circumference. There last are also found to be stronger than the spiral ones.

The Spiderers are in connection with an internal apparatus which secretes the matter they thus elaborate. This apparatus consists of a number of intestine-like canals which are united together, and vary both in number and extent according to the species in which they occur. These canals unite into tubes which open into the Spiderers from whence the thread is extended.

It is by means of these threads that spiders construct the various webs which they throw from one object to another for the purpose of entrapping their prey. It is said that some of the larger species construct webs in which even small birds, such as the humming-bird, are caught and

made subservient to the wants of the spider. No sooner is an insect or other small animal ensnared than the spider, placed in the centre of its net, or in a cell built at its side for the purpose of watching, darts forth, and uses all its efforts to inflict upon it wounds in which it pours the venom contained in its frontal claws. When the creature

thus caught offers too great a resistance, so that the spider becomes endangered, he retires for a time from the contest to renew his strength, leaving his victim secure in his meshes, and gradually getting exhausted from the attempts it makes to escape. When the spider returns he frequently twists the web round and round the body of his victim, and then either at once commences to make a meal of him, or waits till his appetite suggests the proper time for feeding.

Although Spiders are not provided with wings, and are consequently incapable of flight, they have a power of ballooning with their silken threads, by means of which they can make distant journeys through the atmosphere. These aerial excursions, which appear to result from an instinctive desire to seek some more favourable spot for the gratification of their appetite or other cause, are undertaken when the weather is bright and serene, especially in the autumn, both by adult and immature individuals of many species, and are effected in the following way:—They first mount to the summit of an object, and then raise themselves still higher by straightening their limbs; the abdomen is then elevated into an almost perpendicular position, and they emit from their Spiderers a small quantity of viscid fluid, which is drawn into fine lines by the ascending current of air from below, and passing through the animal's body, finding themselves acted on with sufficient force, quit their hold of the earth and mount into the air. It has been sometimes stated that spiders can forcibly propel or dart out lines from their Spiderers; but when placed on spires set upright in glass vessels, with perpendicular sides, all their efforts to escape are unavailing.

The webs named gossamer are composed of lines spun by spiders, which, on being brought into contact by the action of a gentle air, adhere together, till by continual additions they are accumulated into irregular white flakes and masses of considerable extent. The poisonous effects of the wounds of spiders are produced by means of the mandibles, or frontal claws, which are each armed with a movable and extremely sharp point, near to the point of which is a minute orifice, whence there is poured out a drop of poison into the wound. This orifice, which is very difficult to detect, communicates with a canal in the interior of the mandible; this canal proceeds from a gland situated in the interspace of the muscles of the thorax. The gland consists of a vesicle having internally a number of spiral filaments, which are connected together by a membrane in the form of a bag. Although dreadful stories are related of the effects of the bites of spiders on the human body, it appears from experiments made by Mr.
Blackwall on British Spiders, that none of these have the power of producing any ill effects on human beings. There is still wanting good evidence on which to rest a charge of poisoning man by biting him, even against the larger forms of spiders, which inhabit tropical climates.

A curious feature in the history of spiders is the power they possess of reproducing their young without having been broken off. This power, however, is not confined to spiders, as we find it in the Crustacea (Crustacea), and even in the vertebrate animals amongst the Amphibia (Amphibia). In the case of the spiders, it is never a part of a limb which is reproduced, but if a part of a leg is removed, it proceeds to throw off the remainder, and after the next molt the missing member reappears.

The species of the family Araneida are very numerous and have been arranged by naturalists under several genera. They have been investigated with great care by M. Walck-nier, who has made them the special study of his life, and has given us a natural arrangement of them according to their structure and habits of life. A synopsis of this arrangement we subjoin, as by a little study it will furnish an insight into the surprisingly varied habits of this family——

ABRITNATION. The defects in the law, which permitted any agreement to refer disputes to arbitration, if disregarded by any of the parties thereto, to be of no avail, and which allowed arbitrations to come to an end by the death of arbitrators or umpires, or the refusal of any of the parties to proceed thereto, have been remedied by the Common Law Procedure Act, 1844. (Blackstone's 'Commentaries,' Mr. Kerr's ed., vol. iii. p. 17.)

ARCHER-FISH. [Tokok, S. J.]

ARCHIES, COURT OF. The jurisdiction of this Court in Testamentary and Matrimonial Causes has been transferred partly to the Court of Probate (20 & 21 Vict. c. 77) and partly to the Court for Divorce and Matrimonial Causes (20 & 21 Vict. c. 85); and as no act for subtraction of legacies, (20 & 21 Vict. c. 77 s. 33), or for defacement (18 & 19 Vict. c. 41), can now be entertained by any Ecclesiastical Court whatever, its jurisdiction is now confined to a few pecuniary causes, particularly concerned with the Established Church. (Blackst. 'Comm.' Mr. Kerr's ed. vol. iii. p. 93.)

ARCHITECTURE. [Public Improvements].

ARCTIC REGIONS. [Norwegian Passage, S. 2; Arctic Countries and Seas, S. 2.]

ARDEA, ARDEIDE. [Heron.]

ARENICOLA, a genus of Annelidous Animals, referred by Cuvier to the Decabranchiata, on account of their external gills. The general structure and habits of the genus determine most naturalists in placing it amongst the Terre-cidellous Annelids. (Annelida.) The gills are branched, and placed upon the rings of the middle part of the body only. The mouth is nearly, more or less dilatable, but there are no discernible teeth, tentacles, or eyes. The posterior extremity of the body has not only no gills, but is devoid of the silky bristles which are found on every other part. A. Pleurotomum, the Lob or Lug-Worm, is the most common species. It is found very abundantly in the sand of the sea-shore, where its habits afford a close resemblance to those of the earth-worm away from the shore. It is bigger than the earth-worm, sometimes being found nearly a foot in length. It is of a reddish colour, and when touched throws out a quantity of yellow fluid which stains the hand. It is employed by fishermen as bait for various kinds of sea-fish.

AREOLAR TISSUE. [Tissues, Organic, S. 1.]

ARGES. [Praesidea, Hautes.]

ARGILLUS, a genus of Entostracous Crustaceans, belonging to the section Pelecypoda. There is but one species of this genus, the A. filicresta. This little creature is not unknown to fishermen, as it is frequently found parasitic upon various kinds of fish. It was first described by Baker in his 'Employment for the Microscope,' in 1763, under the name of the 'Louse of the Carp and Barbelie and Blackbuck.' It is about the tenth of an inch in length, and is almost as broad as it is long. The head is in the form of a circular-shaped shield. The antennae are short, thick, and two-jointed. Instead of a second pair of foot-jaws it has a pair of circular or disc-shaped suckers, by means of which it attaches itself to the animals on which it parasitizes. These suckers
is admirably constructed for their use. Four muscles are attached to the base of each of these organs, and extend up to their sides. By means of these muscles, and of the force of air in the lungs, the blood is forced through the arteries by a series of pulsations, the pressure of which is examined by the heart. The heart seems to be the chief source of the circulation, and it is, therefore, evident that the blood is in a constant state of motion. It is of course impossible to describe all the vessels of the body, but I shall mention some of the principal ones. Among these are the common carotid, the brachial, the radial, the ulnar, the femoral, the popliteal, the tibial, and the pedal. These vessels are all connected by means of the microscopic vessels, which are so numerous that they can be seen by the naked eye. The body is marked on both sides by a series of ramifications of a dark colour. The female is larger than the male, and is distinguished, in addition to the ovary, by a black mark on each side of the animal. The testicles are not visible, and it is impossible to determine the sex of the animal from the external form. The Argus is found upon various fresh-water fishes. It is most frequently met with near London on the Stickleback, but it has been noticed as occurring on the Carp, the Roach, the Trout, the Pike, the Rudd, and even upon the tadpole of the common Frog. It seems to abound especially when fish are in ill health. Although mostly found upon fish it frequently leaves them, and swims freely about in the water. Fish have an instinctive knowledge of these creatures as their enemy, and it is amazing to watch in a basin of water the efforts which the stickleback will make to avoid its minute persecutor; but the efforts of the fish are in vain, for it is opposed to a creature which has the power of darting through the water with such rapidity as to cause almost an electric shock. The female deposits her eggs from 400 to 1500 in number on stones or other solid bodies. They are laid side by side in rows and glued together. They are hatched in about 25 days, and the young fish remain attached to the mother's tunic until they are able to swim. They are the smallest of the fishes and are found in many of the forms of Entomostraca. The best account, with figures and anatomy, of this parasite, is given in Dr. Baird's "History of the British Entomostraca," published by the Ray Society. Mr. Yarrell has given an account of it in the second volume of his "British Fishes." 

ARIÈGE. [CHEMISTRY, S. 2.]

ARLEIGH. [ARIES.]

ARQUEHITO, a native amalgam, consisting of six parts of silver and one of quicksilver. It has been regarded as carat by many chemists, and it has been used with great success in the mines of Arquehito in Chile. ARREST. The Commissioners of the district Comra of Bankruptcy and the Judges of the Conny Comra have now power to grant a warrant for the arrest of absconding debtors and for their detention for seven days, until a writ of capias can be procured from one of the Superior Courts of law. By this means debtors absconding from the seaports at a distance from London, may be arrested on the spot, and detained until the time fixed by the law. ARTERIES, DISEASES OF. [CHEMISTRY, S. 2.]

ARTERY, from the Greek Arteria, signifying an air-vessel, because the ancient, ignorant of the circulation, and finding its arteries always empty after death, supposed they were air containing air. Why after death the arteries are empty and the blood accumulated in the veins will be explained hereafter. By the term Artery is meant a vessel which conveys blood from the heart to the different parts of the body: a vein, on the contrary, is a vessel which conveys blood from the different parts of the body to the heart. (Classification of the Blood.) All the arteries of the system proceed from two great trunks immediately connected with the cavity of the heart, namely, the Pulmonary Artery, which issues from the right ventricle, and the Aorta, which springs from the left ventricle. (Anatomy.) The arterial system is arborose, that is, the branches which spring from the aorta successively increase in number and diminish in size as they proceed from the heart towards their extremities, so that its internal structure is so much divided into two or more branches, the combined area of which is always greater than that of the trunk from which they spring. The capacity of the branches is estimated to exceed that of the trunks in the proportion of 3 to 1, and the internal diameter of the trunks nearly ends by dividing into two or more branches, the combined area of which is almost greater than that of the trunk from which they spring. The capacity of the branches is estimated to exceed that of the trunks in the proportion of 3 to 1, and the internal diameter of the trunks nearly ends by dividing into two or more branches, the combined area of which is almost greater than that of the trunk from which they spring. The capacity of the branches is estimated to exceed that of the trunks in the proportion of 3 to 1, and the internal diameter of the trunks nearly ends by dividing into two or more branches, the combined area of which is almost greater than that of the trunk from which they spring. The capacity of the branches is estimated to exceed that of the trunks in the proportion of 3 to 1, and the internal diameter of the trunks nearly ends by dividing into two or more branches, the combined area of which is almost greater than that of the trunk from which they spring. The capacity of the branches is estimated to exceed that of the trunks in the proportion of 3 to 1, and the internal diameter of the trunks nearly ends by dividing into two or more branches, the combined area of which is almost greater than that of the trunk from which they spring. The capacity of the branches is estimated to exceed that of the trunks in the proportion of 3 to 1, and the internal diameter of the trunks nearly ends by dividing into two or more branches, the combined area of which is almost greater than that of the trunk from which they spring. The capacity of the branches is estimated to exceed that of the trunks in the proportion of 3 to 1, and the internal diameter of the trunks nearly ends by dividing into two or more branches, the combined area of which is almost greater than that of the trunk from which they spring. The capacity of the branches is estimated to exceed that of the trunks in the proportion of 3 to 1, and the internal diameter of the trunks nearly ends by dividing into two or more branches, the combined area of which is almost greater than that of the trunk from which they spring. The capacity of the branches is estimated to exceed that of the trunks in the proportion of 3 to 1, and the internal diameter of the trunks nearly ends by dividing into two or more branches, the combined area of which is almost greater than that of the trunk from which they spring. The capacity of the branches is estimated to exceed that of the trunks in the proportion of 3 to 1, and the internal diameter of the trunks nearly ends by dividing into two or more branches, the combined area of which is almost greater than that of the trunk from which they spring.
Baring, Bart., an eminent merchant in the city of London. He was removed from school at a rather early age, and placed in the establishment of his father. Having here completed his commercial training he was sent to the United States, where, and in Canada, he for some years conducted the American business of the firm. Here he acquired much of that wide and varied commercial knowledge which he was afterwards enabled to employ to such good advantage on all matters connected with trade and commerce.

In 1798 he married the daughter of William Bingham, Esq., Senator of the United States; and on the death of his father in 1810 he became the head of the great firm of Baring, and was placed hereafter with the House of Commons, where Mr. Baring had long been regarded as a high authority on all commercial subjects. But the ministry had but a short tenure of office, Peel resigned in April, 1835, and the President of the Board of Trade of course became the chief minister. A year later, however, he had created Baron Ashburton. When Sir Robert Peel returned to office, September 1841, the differences of the United States respecting the boundary question excited some anxiety, and Peel requested Lord Ashburton to proceed to America as special commissioner, with powers to conclude a treaty. Both in England and America the nomination was received with satisfaction; and Lord Ashburton conducted the negotiations in so conciliatory a spirit, that Sir Robert Peel declared "that he had never seen in the opening of 1842 an announcement that a treaty had been concluded with the United States, in which "the adjustment of the boundary question was far more favourable to this country than the award of the King of the Netherlands," and that the other points under discussion between the two governments had been arranged in an equally satisfactory manner. In the House of Lords, Lord Ashburton continued to support the policy of Sir Robert Peel until that statesman brought forward his bill for revising the duties of the excise, in which he expected that when he gave to that measure a resolute opposition. After it became law he took little part in politics. He died May 13, 1846, and was succeeded in the title by his son the present peer.

Lord Ashburton cannot be termed a statesman in the proper acceptance of the term. But he brought to the consideration of political questions a clear calm business-like understanding and considerable experience, and though far from an eloquent speaker, his extensive knowledge and unquestioned probity, as well as his high mercantile standing, caused him in his place as a member of either branch of the legislature to be always listened to with respect. As a public man he will be remembered in connection with the treaty which is usually called by his name.

Lord Ashburton was also well known as a liberal patron of arts and artists, not neglecting while forming a valuable collection of pictures by ancient masters to employ living painters. He held the office of trustee of both the National Gallery and British Museum.

**ASIA**

Of late our knowledge of Asia has been considerably augmented. The Russians have steadily and systematically pursued the exploration of their vast dominions in the north; while the English have continued their surveys and investigations in the south and west. The eastern and central portions of Asia alone, particularly the Chinese and Japanese empires, have remained little known; hitherto inaccessible to and unaffected by the rapid tides of progress and discovery which have swept the rest of the world. The Euphrates and the Tigris, with the adjoining regions from the Mediterranean to the Persian Gulf, were thoroughly explored and surveyed by the expedition under Colonel Baring in 1827, and 1836, in the practicality of a steam-boat communication with India by that route. In 1836 an expedition was dispatched by the Imperial Academy of Sciences at St. Petersburg, for the purpose of making a trigonometrical survey from the shores of the Caspian to that of the Black Sea, in order to ascertain the difference of their comparative levels; a question which had excited great interest for twenty-five years previously. This expedition consisted of Messrs. Fuss, Sahler, and Siewidish, who within two years succeeded in making a most accurate measurement of the level of the Caspian sea. The level of the Caspian was 94 feet below that of the Black Sea.

During the years 1834 to 1837 Asia Minor was explored by Callery, De Teyxier, Brant, and W. J. Hamilton, the last of whom, given as a very valuable contribution to the physical geography of the country, and has ascertained the level of many ancient cities. From 1832 to 1837 Fedorow accomplished an important journey through Siberia, between Orenburg and Irkutsk, and between the parallels of 46° and 50° of latitude. He found the depressions and trigonometrical, which formed a new basis for the geography of those regions. During the same years Baer, Pakhomov, and Zimvolka made additions to the geography of Novazembla, and determined a portion of its eastern coast. In 1836 and 1837 Professor Kuzitzky explored the Caucasus, and published the results of his researches in various works, to which a large map was subsequently added.

In 1837 the interesting discovery was made by Moor and Dibner, that the windows in the tower of Belfort, and in the tower of London, are alike at the same level. The same year the great depression extends over the whole of Elb Ghor, comprising the valley of the Jordan as far as the Lake of Tiberias. The first accurate measurements of the Lake of Tiberias were made by the American commissioners in 1841, 1845, and 1848. By Symonds' trigonometrical survey it was found that the depression of the Dead Sea amounts to 121 feet; but his result for the depression of the Lake of Tiberias was shown to be very erroneous. This latter point has been ascertained by the American expedition to be 63 feet below the level of the Caspian. The expedition of Mr. Symonds, which is the result of the labours of the previous observations of De Berton, Russegger, and Wildenbruch.

Ambia, particularly its eastern extremity, was explored by Welles in the years 1836 and 1836; and in the latter year Lieutenant Grittingsen visited the south-western portions of the same country. In 1843 von Wrede made an important journey to Hadramaut, and in 1843 Lieutenant Richard F. Burton, of the Bombay army, in the disguise of a pilgrim, and accompanied by his assistant, Captain H. Yamba, on the Red Sea to Medina and Mecca. In 1846 an interesting journey was made in Kurdistan and Luristan by Major Rawlinson; and an expedition to Kurdistan, under Airawuß, started from Constantinople in 1836, and during two years explored the tribes of Paydar, Pishwar, and those of Armenia, and Kurdistan. The still more recent travels and discoveries of Dr. Layard have greatly increased our acquaintance with the geography of Kurdistan and Assyria. In the regions of the Himalaya Mountains and Afghanistan important additions to geography were made by Burnes, Wood, Vigne, and others. Vigne proceeded as far as Isfandob, and thoroughly explored the valley of Cashmere; while Lieutenant Wood reached the source of the river Oxus, or Amur of the moderns, formed by a lake on the plateau of Pamir, at an elevation of upwards of 16,000 feet above the level of the sea. Cashmere was also visited by Baron von Hügel. Lycia and other parts of Asia Minor were visited by Fellows in 1836 and 1840, and also by Hoxey. In 1844 a Russian expedition under Middendorf was dispatched for the purpose of reaching Cape Taimura, the northernmost point of Asia; but the country they had to traverse was found to consist of immense marshes, uninhabited, and possessing scarcely any animal or vegetable life, and after having overcome considerable hardships the expedition had to return without having reached its destination. About the same time the northern Urmi was scientifically explored by Hofmann, Keyserling, Krusenstern, and others, and rich gold alluvia of great value. The regions on the Caspian were also visited by Reisener and Lehmann. In 1847 an exploring expedition to the Tibetan frontiers was undertaken by the Indian government. This expedition consisted of Captain Cunninghame Strachey, and Dr. Thomson. Previously, in 1844, Lieutenant Strachey had succeeded in reaching the lake of Mansurovassar
A. odorata, the Woodruff, has its leaves six or eight in a whorl, with perfectly white flowers. It occurs in woods, hedge banks, and fields throughout Europe. It is abundant in some parts of England. The whole plant is remarkable for its fragrance when dried.

A. Gynanchica has it leaves four in a whorl, and flowers of a lilac colour. It is found on dry banks and hills in lime

Some species, A. arvensis and A. taurina, are native but are found wild not far from the woods.

ASPIDOPHORUS, a genus of Acanthopterygious Fishes. One species, the A. Europaeus is found on the coasts of England and Scotland. It is known by the name of the armed Bullhead, the Pooge, the Lyrie, Sea-Pooger, Ploog, and Ploog-fish. It is 12 inches long and is occasionally caught by anglers using a bait of 6 inches in length. (Yarrell, British Fishes.)

ASSIGNMENT OF CHATELAYS. [DIll or Saxe, S. 2.]

ASTERNA, a genus of Star-Fishes, including the smallest of the British species, A. gibbosus of Peannant. The Gobious Starlet has a 6-sided body, which is thick and covered below with short spines; the aves are bordered by a single row of spines, and the suckers are in two rows. De Blainville makes out of this species two, which he calls Asterina minimus and A. pravus. A. gibbosus is found very generally around the British Isles, and in the Mediterranean, and on all the shores of Europe.

ASTRONOMY. [Uranography.]

ASTROPHYTON, a genus of Star-Fishes, remarkable for the branching of its spines; of which there are three species, of which A. acutatus is British. It is however a rare animal; and although occasionally found in other places, is most commonly caught off the Shetlands; hence it is called the Shetland Angel. (Forbes, British Star-Fishes.)

ASPUSTUR.

ASUCUNION, the capital of the department of Asuncion and of the republic of Paraguay, in South America, is situated on the eastern or left bank of the river Paraguay, in the latitude 25° 16' south, long. 57° 41' west. Its situation is on the Araguai branch of the Pilcomayo. The ancient city, which stands upon a commanding spot, was built in 1535 by a colony of Spaniards under Juan de Salazar; and from the convenience of its situation speedily became a place of some consequence. It was nearly destroyed by fire in 1625, and the greater part of the houses being built of wood. From this calamity it speedily recovered; and in 1647 was a place of sufficient importance to be erected into a bishop's see. It contains a cathedral, three parishes churches, and four convents of nuns, and monasteries of both sexes; and the river Pilcomayo and the river Paraguay, which form the boundary of the province, meet here. Properly speaking the town consists of only one street surrounded by several lanes and a great number of houses which stand apart and are surrounded by groves of orange tree.

The greatest part of the houses are small and consist merely of a shop with two or three apartments attached to it. Few of the houses have flat roofs; the greater part are covered with tiles. The best buildings in the city are those mentioned above. The inhabitants are of European and Indian descent with the addition of a few negroes; their number is estimated at 10,000. Asuncion carries on a considerable trade in the export of hides, tobacco, sugar, and mate or Paraguay Tea, which is largely used all through South America. Great numbers of horned cattle, horses, mules, asses, sheep, and goats are bred by the farmers, who grow wheat, maize, sugar, tobacco, cotton, mandioc, potatoes, and other vegetables. Honey and wax are produced in abundance; and the rivers supply large quantities of fish.

The air in and about Asuncion is generally temperate and genial; for the greater part of the year the wind blows from the south.

The policy of the late Dictator of Paraguay, Dr. Francisco Pascual Francea, in prohibiting all intercourse with foreigners and with the surrounding states, preserved the republic from the miseries of constant civil and political commotions so characteristic of the neighbouring American republics; but was very detrimental to the trade of Asuncion and of the republic generally. By treaties concluded with great powers in the year 1833, the subjects of Great Britain, France, Sardinia, and the United States are free to navigate the rivers of Paraguay, and to settle and trade in any of the towns of the republic. In the dry season vessels drawing 6 feet water and in the wet season vessels drawing 12 feet can sail up to the city...
Auckland, above which the river Paraguay is navigable for vessels of moderate size for 60 miles.

ATHAMANTINE. [Chemistry, S. 2.]

ATROPINE. [Chemistry, S. 2.]

ATTACHMENT OF DEBTS. A creditor who has recovered judgment against his debtor, may now, on obtaining a judgment, apply for the arrest and sale of the estate of the judgment debtor by third parties; then either by a summary application to a judge at chambers, or where the debt is disputed by the garnishee (the person in whose hands the attachment has been laid), by proceedings similar to those in an ordinary action, for the settlement of the dispute himself, in discharge of his own claim; such payment operating as a discharge to the debtor. (Common Law Procedure Act, 1854.)

AUCKLAND. [Geology, N. W.]

AUGUSTE EDEN, 2nd LORD and 1st EARL OF, eldest surviving son of the 1st lord, was born in 1784. After receiving his education at Eton and Oxford, he entered the House of Commons as M. P. for Woodstock, but was soon removed to the House of Lords by his father's death. He formed a part of the Whig administration as President of the Board of Trade, and was appointed First Lord of the Admiralty by Lord Melbourne in 1834. In the following year he went out to India as governor-general. His administration is marked by the ill-advised Afghan war (1839), and the Bombay Act, which was passed in 1843. In 1849, having been previously advanced to an earldom; the final settlement of the Afghan affair was left for his successor, the Earl of Elibonbridge. Lord Auckland died suddenly of a heart attack on May 6th, 1849.

AUCKLAND ISLANDS, named after Lord Auckland, lie in 51° S. lat., 168° E. long., about 800 miles S.S. from Van Diemen's Land, and 180 miles S. from New Zealand. The group, which was discovered in 1806 by Captain Briscoe, consists of one large island and several smaller ones. Auckland, the largest of the group, is about 30 miles long and 15 miles broad, and contains about 100,000 acres. The entire group is of volcanic formation, composed of greenstone and basalt, and presenting a picturesque appearance. Auckland, the highest hill, situated on Auckland Island itself, is estimated at about 1350 feet above the level of the sea. There is a marked difference between the west and east coast of Auckland Island, the west coast presenting towards the sea a line of precipitous cliffs, whereas the east coast exhibits here and there a fine sandy beach, upon which the sea scarcely breaks, and is intersected by numerous streams and inlets; while the elevated land from the sea-bay to the summit is clothed with luxuriant vegetation and covered with a thick layer of vegetable mould, which is three feet deep at some places. The eastern coast contains two principal harbours, formed by inlets of the sea, which reach to within two or three miles of the western coast, and are only six miles from each other. At 30° S. lat., at the western extremity of the island, is protected from the long southerly gales by a range of small hills, and has a good tenacious clay bottom. Port Ross contains an upper inlet called Laurie Harbour, about four miles wide, and perfectly landlocked; while the steep beach on the southern side of the harbour affords great facility for clearing and reloading vessels.

The climate has been described by Sir James Ross, Captain Briscoe, and other navigators who have visited the islands, as mild, temperate, and salubrious. The temperature in the valleys is scarcely ever over 58°, or lower in summer than 78°. The weather is generally good, but there are occasional high winds and heavy rains. Auckland Island is abundantly supplied with small streams. The soil is well watered; the hills, except a few of the highest and the elevated terraced fields, are covered with moss and a kind of tall grass. Dr. Hooker notices the Auckland Islands as remarkable for the variety of their vegetable productions, eighty flowering plants having been found; and over 5000 varieties of mosses, till then unknown, have been noticed for their beauty and novelty. The only animals found on the island are goats and rabbits. Pigs were left on Auckland Island in 1805 by Captain Briscoe, on his second visit, and these animals have greatly increased in numbers, and are now an extremely valuable article of food. Fowls, ducks, and small birds were found. On the heights petrels breed in considerable numbers. Hawks, gray ducks, snipes, cormorants, and the common shag also inhabit the islands. Fish are plentiful. The coast of Auckland Island, and the rocks are covered with limpets, while the whale fishing carried on in the neighbourhood may yet become very valuable. Sir James Ross mentions that while he was in Laurie Harbour many sperm-whales came into the anchorage.

The Auckland Islands were granted by government to the Messrs. Enderby on advantageous terms, in consideration of the services rendered by their father to this country, as also for the more recent discoveries of the southern continent by Captain Enderby and his crew. A company was formed, and incorporated as 'The Auckland Islands Company,' to which the Messrs. Enderby ceded their privileges, obtained a charter of incorporation on the 16th of January, 1849, for the purpose of prosecuting the whale fishery in the southern seas, and was chosen as the head station of the company, from the superior facilities it affords to whaling vessels. The islands were uninhabited until the Southern Whale Fishery Company, under the conduct of one of the Messrs. Enderby, made a settlement here in 1848.

AUDOUIN, JEAN VICTOR, was born at Paris on the 7th of April, 1797. His early education was intended to fit him for the law, but his inclinations were towards the study of organic nature, and he accordingly gave up the study of medicine. His mind was early directed to the study of the natural history of insects. The first paper which he published was a description of an animal belonging to the class Insecta, in 1816, and from this date to the time of his death, his labours in this branch of study were incessant. The results of his investigations were published in the form of contributions to the various journals or in the Transactions of societies. These papers were numerous, and they are all valuable.

He is best known for the anatomy of the Insecta, and especially those on the Annelida, introduced him to the notice of Cuvier, Geoffroy St. Hilaire, and Latreille, with whom he lived on terms of intimacy, and from whose instruction he obtained those enlarged views of the relations of the animal kingdom which are so conspicuous in his admirable works. In 1828 he became connected with M. Milne-Edwards in researches upon the Crustacea and Annelida, which resulted in a great addition to existing knowledge on the subject of the minute worms and various other invertebrate animals. In the same year he became assistant to Lamarck and Latreille in the Jardin des Plantes, Paris, and on the death of the latter he was appointed professor of entomology in the museum attached to that institution. In his lectures here he paid particular attention to those insects which were injurious to vegetation. His investigation of the economy of insects was very extensive, and only a small portion of the matter he had collected was published before his death. He left behind him fourteen quarto volumes of manuscript on this subject, with numerous illustrations, and a considerable number of charts of the distribution of insects in France, prepared and published a work, entitled 'Histoire des Insectes nuisibles a la Vigne, et particulierement de la Pyrale qui d&egrave;vaste les Vignoles des D&eacute;partements de la Haute-Garonne, des Alpes Maritimes, des Pyr&eacute;nees-Occidentales, de la Haute-Garonne, de la Charente-Inf&eacute;rieure, de la Maine, et de Seine-et-Oise.' It came out in six parts quarto. The first part appeared in 1840, but the last did not appear till some time after the author's death, in 1845. The work treats not only of the natural history of these insects, but also of the means of preventing their increase and of destroying them. It is illustrated with beautiful plates, after drawings by the author, and, whether regarded as an example of careful observation, and the application of its illustrations, is probably one of the most valuable ever contributed to entomology.

Audouin fell an early victim to the pursuit of his favourite science. He was called to the bar by order of the Emperor of France, for the purpose of investigating the habits of the insects which injure the olive-plantations. Here he exposed himself to the cold and wet, which brought on an attack of apoplexy, of which he died on the 9th of November, 1841. On the day of his funeral the sales were delivered at the Faubourg St. Antoine, under the direction of M. Serres, president of the Academy of Sciences; M. Chevreul, director of the Museum of Natural History; M. Milne-Edwards, and M. Blanchard. Audouin had collected a fine museum, not only of individual insects, but of the different species that he had discovered. They were exhibited after his death at the museum of the Jardin des Plantes. His library was large, and when sold by public auction at his decease realised 30,000 francs.
for the study of the habits and the structure of insects. In all his more important works on entomology, it is evident that he did not regard insects as the end of his inquiries, but that he looked upon them as a great class of phenomena, illustrating the general laws that were deducible from the study of the whole animal kingdom. With him external forms were only regarded as dependent on an internal structure, which in its development, and the functions it performed, corresponded to the whole animal kingdom. It was thus that he was led to investigate the annulose subkingdom of animals, and succeeded in adding to science so many important facts which assist in indicating the true relation of these animals to one or the other division of the animal kingdom.

(Abridged from the Biographical Dictionary of the Society for the Diffusion of Useful Knowledge.)

AUDUBON, JOHN JAMES, an eminent American ornithologist, was born in the county of Lancaster, on the 4th of May, 1780. Both his parents were French. His father, who was an ardent admirer of the beauties of external nature, endeavoured from his earliest years to foster in him a similar taste, and especially directed his attention to the many tribes of birds which inhabited that part of the state in which they resided. The boy's passion for the study of birds and everything connected with them, soon outran his father's promptings. While still a child he obtained possession of several of the splendid-plumaged specimens of American birds; and before he was about fourteen, his father took him to Paris, and placed him in the studio of the celebrated David. Here, though he neglected the study of the higher principles of art, he became a skilful draughtsman; and satisfied with having obtained the competency of a profession, resolved to become a draughtsman of the first order. A few years afterwards he was recommended by a celebrated ornithological illustrations, the boy determined to become a draughtsman himself.

Feeling his deficiency in the elements of drawing, he applied himself with great assiduity to acquire the ability in that branch of art, and lengthened it when he was about fourteen, his father took him to Paris, and placed him in the studio of the celebrated David. Here, though he neglected the study of the higher principles of art, he became a skilful draughtsman; and satisfied with having obtained the competency of a profession, resolved to become a draughtsman of the first order. A few years afterwards he was recommended by a celebrated ornithological illustrations, the boy determined to become a draughtsman himself.

In 1798 his father gave him a farm in Pennsylvania, near the village of Schuylkill, but he badly neglected his agricultural duties. Of his occupations here, he says, "my rambles invariably commenced at break of day, and to return wet with dew and bearing a feathered prize, was, and ever will be, the highest enjoyment for which I have been fitted."

At the age of twenty-three he went to Philadelphia, and there he made the acquaintance of Mr. Martin Davis, a wealthy young merchant, who shared his after fortunes. For nearly twenty years he now pursued commerce (nominally) and his success was what may be expected. He removed westward to Louisville, and there first met Wilson, with whom he was afterwards closely connected. In 1810 he sailed forth on a great exploring expedition, and sailed down the Ohio with his wife and child, bird-sketching as he went. In the next year he explored Florida. Finding the joint pursuit of business and science impossible for him, he soon abandoned his nominal business altogether.

On the 5th of April, 1823, he visited Philadelphia, where Dr. Mease, his only intimate friend in the place, introduced him to Charles Lucien Bonaparte, prince de Muratbugno, and then to the lapidary, Dr. Chaloner, in whose cabinet he published a splendid continuation of "Wilson's Ornithology." The prince warmly encouraged him in his plans, and he now began seriously to contemplate publication. From Philadelphia he went to New York; and thence, along the coast line of the Atlantic, to New England, through all our northern forests. It was now he projected, in a methodical manner, his famous publication of illustrations, which he divided into numbers, to each number five plates, according to the general plan of Dr. Wilson, indicating all the dimensions of the science; and very often they are presented also in the most capricious attitudes, but with the strictest fidelity to nature.

After a ramble of eighteen months, he returned to his home, to Mount Arden, in the surrounding forests, and there passed the winter. Without the means of publishing his great work, the third part of which, when it appeared, cost 40l. per copy to the purchaser, he landed at Liverpool in 1826. His letters of introduction procured him a cordial, and even enthusiastic, reception in that town, in Manchester, and in Edinburgh, where he commenced the publication of his illustrations and descriptions of the "Birds of America." The work, however, was quickly transferred to the hands of London artists. In September 1826, he once more visited France, where he was most hospitably welcomed by the scientific world. Baron Cuvier presented a panegyric of him before the Institute. Charles X., Louis Philippe, and other great personages, the Duke of Kent, the Duke of Cambridge, Humboldt, the Institute, and others, joined his subscription list. By the 25th of November 1826, the eleventh number of the work, and 100 plates, had appeared.

He now determined to revisit America for the purpose of refreshing supply of materials, and to compete with back with him to Europe. On the 1st of April he set sail, and in about a year he returned with Mrs. Audubon. Having again gone back with his wife to America in August 1831, he proceeded to Florida, explored the forest of Muna, made a voyage to the Gulf of the St. Lawrence and the coast of Labrador, and visited Newfoundland and Nova Scotia. On the 28th of April 1833 he held at New York, where now the greatest honour was paid to him, an exhibition of his illustrations of American water-birds. In 1834 he again went to Florida, and thence to Texas. The scientific fruits of Audubon's romantic rambles had procured him many tokens of respect. He became a Fellow of the Linnean and Zoological Societies of London; of the Lyceum Natural History Society of Philadelphia; of the Geological Society at Paris; of the Wernerian Society of Edinburgh; honorary member of the Society of Natural History at Manchester, of the Royal Scottish Academy of Painting, Sculpture, Architecture, and Agriculture; of the Society of Arts; and of the American Philosophical Society. Audubon's book was the largest and grandest which had been published on Ornithology. Every sort of bird is engraved, male, female, and young. The drawings are admirable; and the descriptions are second in merit to Audubon's life of exploration and study was prolonged to the ripe age of 71. He died on the 27th of January 1838, at Minnis-
after a journey of excessive difficulty and privation, established the startling fact that there is not a single water-course on the whole coast of Australia from Moreton Bay to King George's Sound, a distance of more than 1,500 miles.

Whilst these attempts were being made to penetrate towards the interior from the south, Captain Wickham, in Her Majesty's Sloop *Erebus*, was endeavoring to reach the northern coast.

In command of the Beagle, he carried on a survey of the intertropical shores of the continent, which led to the discovery of two considerable rivers—the Victoria, in 14° 29' S. lat., and the *Beagle* in 13° 54' E. long. Captain Stokes succeeded Captain Wickham in the command of the Beagle, and penetrated nearer to the centre than had been done before.

Captain Sturt, in his last journey, left Adelaide on the 16th August, 1844, and followed the course of the Murray as far as its confluence with the Darling, then struck northwards. Crossing vast tracts of barren ground and the great stony desert, on the 9th of September, 1845, he reached 24° 50' S. lat., 126° E. long. He arrived at Adelaide on his return, Jan. 19, 1846.

Sir Thomas Mitchell spent the year 1846 in an exploring journey into the interior of tropical Australia, making his way immediately to the westward of the mountain range which separates the east and west coasts, and to the coast of Moreton Bay. He had to pass over a great deal of dry and barren land, but he also discovered a large extent of singularly beautiful and rich country, especially about the head of a river which he discovered near 28° S. lat., and which he named the Hunter. He was determined to cross the country, however, was unable to continue his way to the head of the Gulf of Carpentaria, the main object of the journey; but as he was strongly of opinion that the Victoria would be found to fall into the Gulf of Carpentaria, Mr. Kennedy, after the return of the expedition, was despatched to continue the search along its banks. He found that the Victoria, called by the natives the Barcoo, soon turned to the south-west towards the interior. He followed it for about 100 miles beyond its regular course, and was left by the river, which dwindled away and was lost in the sand in 26° 15' 9" S. lat., when, owing to the failure of water, he was compelled to return. Making his way homeward by a route much to the west of that by which he as well as Mitchell had before proceeded, he discovered a wide extent of rich and well-watered pastoral country.

Dr. Leichhardt started on his overland expedition from Moreton Bay to the north coast, at the end of September, 1843, and proceeded to the end of the year 1845. In this journey Dr. Leichhardt reached a large extent of beautiful and fertile country. At the end of 1846 he started on a still more difficult and perilous journey, from the eastern coast to the western, across or on the skirts of the great stony desert, which was traversed by Sturt in 1844, 1845, and 1846. In this last and fatal journey he found a country of remarkable beauty and fertility—a discovery which he, with characteristic ardour, returned 300 miles to the nearest frontier station to report. The richness of this part of Australia is therefore well established; and although the frequent failure of the streams is at present a complete bar to any successful squattting settlements, little appears to be wanting for the development of its resources besides the construction of dams, by which the channels of many of the streams might be at once converted into canals for the reservation of the water, and of reservoirs, for which the undulations of the land afford peculiar facilities. Dr. Leichhardt, in this last journey, was accompanied by Mr. Loyd, whose name has been given to one of the rivers on the east coast. Dr. Leichhardt has not since been heard of, and there seems to be hardly a doubt that he and all his party have perished in the great central desert.

The latest expeditions on the interior of Australia was that of Mr. A.C. Gregory, from the north-west coast which was explored at Moreton Bay, and proceeded by sea to the mouth of the Victoria River. The horses were landed at Point Pierce, in Sept. 1855; and on the 5th of May, 1856, the party was carried in boats to a bend in the river, and thence by land to the country to the south of the Victoria River, having penetrated the interior deserts to 18° 29' S. lat., 127° 30' E. long. On the 21st of June Mr. Gregory left the encampment on the bank of the river, accompanied by six persons. The arid nature of the country compelled them to increase the latitudes to 15° S., after which they kept parallel to the coast as far inland as water could be found in the rivers, the greatest distance from the sea not exceeding 100 miles. Proceeding northwards along the south coast, they reached the *Beagle* in Sept. 3, and made some ineffectual attempts to proceed to the south-east. Want of water compelled them to pursue a route parallel to the coast, to 17° 20' S. lat., when the Gilbert River enabled them to follow a south-eastern course, reaching 21° 40' S. lat., Oct. 19, when they reached the Burdekin, Oct. 16. Their route was then along the right bank of that river to the junction of the Suttor River, which was followed up to the Beylano. Tracing the Beylano to its junction with the *Beagle* River, they reached the junction of the Comet and Mackenzie Rivers, whence their course to the Dawson brought them, on the 22nd of November, to the farthest station of the settlers, whence they proceeded to Brisbane.

Of the *Beagle* River, Dr. Leichhardt, 1846.—The Australien Alps, which occupy the south-eastern angle of the Australian continent, rise to an elevation of 7000 feet above the sea, and their summits are perpetually covered with snow. In the rest of the mountains-range which flanks the eastern coast, the loftiest summits seldom exceed the elevation of 4000 feet, though there are some which rise to 6000 feet.

North of 33° S. lat. the principal valleys are transverse, and the course of the rivers is consequently west and east. The result is that the plains are generally level, and free from the great degree of declivity, however, considerably towards the south. Its entire length from its source in the Liverpool range is above 200 miles. It is navigable for small vessels up to Morpeth, about 35 miles from its mouth. Its two principal tributaries, the Loddon and the Lachlan, are both navigable, the former being 200 miles from its mouth, the latter only 140 miles. The upper Loddon, or Loddon Creek, is navigable for about 30 miles from its mouth, and is divided into two branches, the main course being navigable for about 18 miles, and then running into a series of lakes, which are in reality the mouths of two branches of the river, the one of which is about 18 miles long, and the other 13 miles. Its estuary stretches about 30 miles across the country, being in places 13 miles in width.

On the north of the Murray is a large long, narrow, almost navigable lake, which affords a fair passage between the north and south, and is navigable to a depth of 10 feet in places from its mouth, where the ship navigation is stopped by a rocky shoal, but boats ascend 40 miles higher. The Moreton Bay district and the country northward appear to be free from the drouths which are so destructive in the southern parts of the country.
North of Moreton Bay the mountains recede to the west, and about 20° S. lat. become much lower, losing in fact, in a progressive manner, all their former altitude. The coast is comparatively easy access to the extensive pastoral regions which Sir Thomas Mitchell and Dr. Leichhardt have described in the interior. On this part of the coast, near 22° S. lat., is Fort Bowen, near Broad Sound, the outlet of the Nanga and York inlets. Port Bowen is well adapted for steam navigation, and appears likely some day to become an important harbour. The country northward is almost unknown. The entire north-eastern coast, from 22° S. lat., is bordered by small islands and rocks forming what are known as the Narran Islands, which descends from the western slopes; it has a large body of water, but on account of sand-hanks is un navigable. The Wimmers and other streams which flow northward from the Grampians are lost in shallow lagoons, which are formed in the sand; the mouth of the largest of these is the Yarra Yarra, which rises in the mountains east of Melbourne, flows past that city, below which it is navigable. The country north of these mountains, which forms the northwestern part of Port Phillip Bay, has an extinct crater on its summit. Between this and the Murray are low ranges of hills generally running parallel to the shore, and separated from each other by level plains, which are subject to inundations, but afford excellent pastures. The western shore of Spencer's Gulf is Port Lincoln, the best harbour in South Australia, and around it is much fertile country. Off the entrance of Spencer Gulf lies Kangaroo island. West of this, to Streaky Bay, is a mountainous tract, known as Gawler's Range, the summits of which increase in height towards the west, where they attain an elevation of 2000 feet. West of Streaky Bay, and extending into Western Australia, is a waste and dreary country, covered merely with heath.

Of the whole of the western end of the continent is included in Western Australia. The coast from Port Lincoln to King George's Sound forms the Great Australian Bight, and presents a very remarkable appearance; from Streaky Bay to Cape Arid, about 600 miles, there is a succession of cliffs from 300 to 600 feet high. The interior here, as far as it has been explored, consists of apparently interminable plains; no river is visible and no fresh water procurable. Immediately west of the Great Australian Bight, lies the Arid Peninsula, which, between the month of Albany, the town of which is the town of Albany, the country improves considerably. The surface is much broken, and there are lofty hills and rapid streams. From the south-west of the Arid Peninsula, the Avon and Darling Range of Mountains, which terminates there in Point D'Entrecasteaux and Cape Leeuwin, runs northward as far as Shark Bay, at a distance of from 50 to 100 miles from the coast, and rising from 600 to 3000 feet above the sea. Portions of these connected mountains are known as the Gairdner's, Moreby's, Herschel, and Victoria ranges. The highest summit, Tul-banop, is said to attain an elevation of 5600 feet. The extensive plains are covered with a rich deposit of red sandstone or limestone. They are mostly barren, but at some distance inland near the Blackwood River, which falls into the sea at the western angle of Flinders Bay, Mr. Roe found considerable forests of timber-trees fit for naval purposes; he also discovered good coal in two or three places. East of the mouth of the interior are sandy deserts. Swan River has a bar at its mouth, but within it is navigable for some distance. The bed of the river rises rapidly from its mouth, and some distance inland the channel is frequently dry. Perth, the chief town of Western Australia, is built at the mouth of Swan River.

Along the north-western coast the country differs considerably from any part of the continent hitherto described. Instead of a lofty range of hills rising at a short distance from the shore, the coast from North-West Cape along the Dampier Archipelago, to Roebuck Bay, and thence along Buccaneer Archipelago up to the rocky promontory, near Prince Regent's River, is a low sandy level, covered with salt-leaved plants. Near Prince Regent's River the coast is broken into bold granitic head-lands, some of which are 800 to 1000 feet high. Numerous islands, some of them hasaltic, line the coast, and the scenery is wild and striking. Mounts Trafalgar and Waterloo rise to the height of 900 feet, and as described from the sea, they appear to consist of the coast as far as Cambridge Gulf, are low hills. At Cambridge Gulf a river of some importance falls into the sea. It was named the Victoria by its discoverer, Captain Stokes, R.N., who ascended it in 1838, and named it the Ransome, which he called the Fitzroy Range. In its lower reaches the Victoria flows through low, sandy, mangrove flats, which at its mouth have been cut into numerous islands, covered during floods; but higher up, its banks are hilly and very fertile. The Somerset, a tributary river of the Macdonald range, which consists of hills averaging from 400 to 600 feet in height. Nearer the shore, between Cambridge Gulf and the Gulf of Carpentaria, these hills become lower, and terminate generally in sandstone cliffs, seldom exceeding 60 feet in height, and sometimes forming a high ledge of 840 feet. From the Mosquito Flats a connected range, from 700 to 800 feet high, runs off to the north-east. Stretching away from the river towards the interior Captain Stokes saw apparently interminable plains.

Near Port Eucla, the main rivers of the interior, the Paroo, Murchison rivers is the Macdonald range, which consists of hills averaging from 400 to 600 feet in height. Nearer the shore, between Cambridge Gulf and the Gulf of Carpentaria, these hills become lower, and terminate generally in sandstone cliffs, seldom exceeding 60 feet in height, and sometimes forming a high ledge of 840 feet. From the Mosquito Flats a connected range, from 700 to 800 feet high, runs off to the north-east. Stretching away from the river towards the interior Captain Stokes saw apparently interminable plains.

The shores of the great Gulf of Carpentaria are almost invariably low and flat, and generally covered with mangroves. The banks, which are of clay or sand, are seldom more than 50 feet above sea level; but along the eastern sides there are more small trees, but the shore is one wide, low, level, sandy waste. The rivers which fall into the gulf are few and unimportant. One or two inlets which appear to be the mouths of rivers, have indeed not hitherto been explored, but there is nothing to lead to the belief that they differ from those which have been followed up. The chief of the rivers in the Gulf of Carpentaria are the Flinders and the Albert, but like the others they consist merely of short and narrow streams opening into wide shallow estuaries. The Albert was ascended by its discoverer, Captain Stokes, in a boat for about 50 miles from its mouth. He found it bordered by open woodlands of acacias and gum-trees. When unable to ascend the river further, he made his way on foot south-west towards the interior of the country, and found it to consist of vast and apparently boundless grassy plains, relieved by occasional clumps of gum-trees; he named them the plains of Promise. Another river, which he named the Albert, was also found by Captain Stokes, and was bordered by alluvial flats and extensive extensive small creeks. The coast of northern Western Australia, that the adventurous Kennedy was murdered by the natives.
of drift and sometimes 100 feet high, running in parallel lines as far as the sight could reach. The dryness and the heat of the climate is intolerable. In the midst of this plain, near 25° 33' S. lat., about 30° E. long., is a considerable and quite sterile desert, which extended, as far as he could ascertain, about 80 miles in length and 35 miles in width. Near 27° 33' S. lat. Captain Sturt discovered a sheet of water which he called Murrumbidgee Creek, extending eastward and westward for nearly 80 miles, and on each side in arid sand.

It has been supposed that this creek may be in seasons of flood connected with the singular horse-shoe shaped depression known as Lake Torrens, which as already mentioned in part encircles the mountain at the head of Spencer's Gulf and that on the other side it might unite with Sturt's Stony Desert. Lake Torrens, it may be as well to mention, though called a lake, is not filled with water, but is merely an extensive depression, the bed of which is for the most part dry, with occasional uncocunced pools and muddy holes. In seasons of great floods it would no doubt be filled with water, which it is possible may find an outlet in Spencer's Gulf. In a country where rain was abundant Lake Torrens would of course be a permanent lake, according to the ordinary occupation of that term.

Generally it may be said of the continent, that the ranges of mountains mentioned as stretching along the south-eastern and eastern coasts, in some places come close down to the shore and leave but a narrow strip of sandy or dry or wet plains, with occasional sandy tracts, to extend between them and the sea. Towards the interior, beyond and nearly parallel with the mountain ranges, are undulating downs of moderate height extending between them. Mr. Darling Downs, discovered by Mr. T. Mitchell, the Goulburn, Balmain, and the New England district, with vast fertile plains, lying along and between the great rivers. These downs afford the chief sheep run, and to the cattle pastures. Farther inland are wide-spread marshes and worthless jungle, and enormous baron, arid, and sandy, or stony deserted wholly uninhabitable, and which have hitherto baffled all attempts to explore them. No dense forests have been discovered in those sections of the country in the Murray Bay district and in tropical Australia. The trees are almost invariably light of foliage and very marked in character. The herbage is thin; the grasses are nutritious, but generally grow in detached clumps.

The river system of Australia, as far as known, is peculiar. Many of the rivers of the interior are lost in the sands, others are subject to immense overflows so as to convert in the wet season a large portion of the adjacent country into vast swampy land, and by season their places quite dry and they are converted into a number of scarcely connected lakes. Few of the rivers which fall into the sea are navigable, and nearly all have bars or other encumbrances at their mouths.

The Murray river system at its junction to the other known streams of the Australian continent. The basins of this fine river are in the deepest recesses of the Australian Alps. The headwaters of its immediate tributaries extend from the 36th to the 32nd parallel of latitude, and from 146° to 149° of longitude. It reaches the low lands near 36° S. lat., 147° E. long., not far from the rising town of Albury. Its course from this place is exceedingly tortuous, the curvatures being short, abrupt, and very numerous. The whole of the upper course is obstructed by sand shoals, and snags formed by trunks of trees, and other objects which have caught in the bed of the stream; but there appears to be no insuperable obstacle to the clearance of the channel if there were sufficient intercourse to render it profitable. It would however be a costly and useless enterprise, and unless otherwise an embankment were formed, as the river is subject to anual overflows, when the country for a considerable space on both sides is converted into a swamp. These floods prevent agricultural operations being carried on. The banks of the Murray, above the junction of the Murrumbidgee and the Murrumbadbée rivers. No river here falls into the Murray on the right bank, but there are numerous creeks which pass from the Murray to the Edward River, which is a great arm of the Murray which runs between the main stream and the Murrumbidgee for many miles, and receives near its eastern end the Billabong River. A large portion of the level country between the Murray and the Darling is a swamp; much of the remainder is covered by the Edward, and the many connected channels, and the innumerable lagoons, or 'billabongs' as they are called by settlers. Many of these lagoons have on the top a thick coat of salt; indeed the whole Murray district is so covered in this mineral. The soil is generally a grey clay. The Murray receives the Murrumbidgee in about 143° E. long. The river is here about 350 feet broad, from 12 to 20 feet deep, and flows at the rate of 25 miles an hour. In 141° 30' it receives the Murrumbadbée River, which is here 100 yards wide and rather more than 15 feet deep. As far as the junction of the Darling the Murray continues to flow to the west-north-west, but afterwards it passes between some limestone cliffs and its course changes to the west, and the river is considerably increased in size. After passing the meridian 140° it trends to the south; and in this direction it flows without receiving any tributary of consequence till it expands at its mouth into the Lake Victoria, which is 60 miles long and 40 miles broad, but generally very shallow. The water of the lake is brackish and it communicates with the sea at Encounter Bay by a passage impracticable even for boats. The river Murray however is navigable for vessels of considerable burden, being navigable for steamers of 500 tons; and can be followed from 20 to 25 feet deep. It appears certain indeed that it is navigable for steamers of light draught up to its junction with the Darling; and recent explorations have shown that it is possible to ascend the river till the point of its junction with the course of its windings, the length of the Murray is probably not less than from 1300 to 1500 miles. Little influenced by the sudden floods to which the other Australian rivers are subject, its rise and fall are equally gradual. Instead of forming a great sheet of water as do the countries on the margin of the Mediterranean, it is a marsh or exhausitng itself over extensive plains, its Never-failing fountains have given it strength to cleave a channel through the interior desert, and carry its broad and trans- parent waters to the sea. The Murrumbidgee is the first addition to its waters from the eastward in the month of July, and rises at the rate of an inch a day till December, in which month it attains a height of about seventeen feet above its lowest or winter level. As it swells it fills in succession all its lateral creeks and lagoons, and ultimately leaves many small lakes and rivers.

As it rises, so it falls, gradually. No river falls into the Murray after its confluence with the Darling, nor doess any fall into the Darling from the west after it reaches the low lands of Australia, as all the streams are in the north or north-east.

**Geology, Mineralogy, &c.**—We possess so few facts, comparatively, respecting the geological structure of Australia beyond an enumeration of a somewhat limited number of localities in which granite, limestone, sandstone, and other rocks are generally described, as by their isolated occurrence, that it would be of little use to attempt to give a general description, or even to institute comparisons with the known European deposits. Here we shall do little more than enumerate the principal varieties of rocks merely stating as a general law that, as far as known, the geological formations are almost entirely of the kinds commonly termed primary and tertiary. Secondary rocks are scarcely anywhere met with. It is however premature to draw general conclusions. The mineralogy of Australia is excelling, but presents an extraordinary amount of attention, and the geology also is being with more or less care and skill investigated, so that additions are almost daily being made to our previous store of information. The results will be more conveniently given in a more extended work. The direction of the mountains and the strike of the rocks of which they are composed are almost invariably north and south; the only important exception being on the north side of the continent, where there is an inclination to the east and west. Secondary rocks are described as occupying the south-eastern and eastern portions of the island, having frequent masses of metamorphic rocks in connection with it. Much of the granite is the granite proper, and its granular structure, its schist and phylspar and hornblende so largely abounded as to modify the granitic type; in some places the hornblende predominates, and frequently, as between Armuprior and Braidwood, the granite passes into siltite and porphyry. Examples of all these varieties are met with in the Australian Alps, about
The sources of the Murray, in Moonee, in the Currambene Range, the Araluen and the Main ranges, Mount Victoria, and many other parts of the eastern side, are well watered, and vary as usual very much in their mineralogical structure. Very commonly they consist of basalt, greenstone, and various argilloides, and have an overlying deposit of conglomerate grit and sandstone. The trappean regions of Manero, which may be taken as illustrative of the trappean regions of the south-eastern portion of Australia, is of this character. According to the Rev. W. B. Clarke, the government commissioner, "the physical features of this region are precisely similar to those of the Grampians and Lakes district in Victoria. The division between granite mountains (here the Snowy and the Coast mountains), which it has filled up, sending its streams of consequently lava to considerable distances on each side of the general line of the axis of eruption. In Manero this axis has a north-west and south-east direction, and ranges from the head of the Towamba towards the principal bed of the Murrambidgee, at the northern extremity of the Snowy Mountains, or Australian Alps. Connected with this general trend of the trappean, the discovery of space, their texture, structure, and composition, prove them to have a common relation with each other, and with the great development which has occasioned the remarkable connection between the Snowy ranges to the west and the Coast district. The running discloses in the interior, the general division between the waters flowing on the northern side to the Murrambidgee, and on the southern to the Snowy River. It is to the trappean outburst, which is undoubtedly a result of the same agency, that the broken and discursive condition of the pressure of the vast mass of snow to the Hindmarsh, Wallace, and Wellingbury is in a considerable measure due; it has directed the principal drainage of the country in two opposite courses, and has produced innumerable physical discordances in the features of the country.

A large portion of the basin of the Murrambidgee is occupied by quartz phorphyry, which is also largely developed in many other places. Porphyritic and basaltic dykes are very frequent. Very fine examples of columnar basalt occur at Coroo and elsewhere on the great dividing range, and not unfrequently in other parts of the great mountain district. Serpentine, soapstone, pitchstone, and a fine red Jasper are frequently met with in the trappean districts. Laminated, compact, and fossiliferous limestones are found in numerous places. Coal and the running Tree is limestones and marbles, a little below Glenrock, the limestone is seen passing into staurolite marble, white and crystalline; black marble occurs in strata in Bourgu Creek. A bed of limestone, which appears to agree with consideration in thickness both north and south of Bathurst, has been termed "bandonation." The coal and associated bed of sandstone and shell, which occur extensively on the eastern coast from Port Stephens to Botany Bay, occasionally ranging into the interior, have been considered equivalent to the coal-measures of Europe, merely from their mineralogical characters. What the age of this Australian coal deposit may be we have no means of accurately judging; but it is worthy of remark, that a fossil plant (Glossopteris Browni) detected in it is also discovered in the trappean district, and its presence itself appears to be abundant and generally of good quality. Coal also occurs in great quantities on the Warrumbungle Mountains and elsewhere in the mountain district of New South Wales. Mr. R. in 1846 discovered coal by the north of the Fitzgerald River, about 140° 40' E. long., 20° S. lat., and by the Charles River some distance to the west, both places being in or near to Daintree Island and easy of access. It has also been met with in several other localities.

Sandstone rocks extend very generally through the mountain district. Sydney is built upon a sandstone deposit, which extends as far inland as Mount Victoria, and forms the bulk of the Blue Mountains. Its southern limit is Fort Stephens. The sandstone in its various stages, from the very fine-grained, argillaceous, and calcareous, in parts they appear very similar to those of the old red-sandstone formation of England. Found in conjunction with fossileous lime- stones and conglomerates they closely resemble those of the Devonian system. Both the limestones and sandstones are of exceeding value for economical purposes. Sandstones and limestones are the prevalent rocks of the shores of Western Australia. In North Australia is a great sandstone plateau rising 1800 feet above the level of the sea.

The slate and other schistose rocks are numerous and important. A quartziferous schist is the predominant rock of the country between the Canobolas and the Carlingford Valley, and it prevails extensively throughout New South Wales and the eastern part of Victoria. The soil which covers this rock is generally poor, but the rock itself is rich in minerals. The slates are commonly grey, bluish, and greenish in color, and have a glistening appearance. The slates are not infrequently intersected by veins of quartz and trap. Grey or brownish-white, soft or hard, felafal beds of schist occur in conjunction with the slates, passing "into a true girt or sandstone, and becoming occasionally very quartzose, bands of quartz and thin fibrous veins of quartz traversing them." Clay-slates and other argillaceous deposits are also general. The clays and other tertiary deposits occupy a wide area; in fact, it is probable that the whole interior is formed of horizontal tertiary deposits, broken here and there by tracts rising from them, like islands from the bed of an inland sea. Good brick and pottery clay is found.

Australia was not until lately considered rich in minerals. The first gold was discovered in New South Wales in 1846, and still more the extraordinary discoveries of gold in 1851, however led to investigations which have gone far to show that Australia is mineralogically one of the richest countries in the world. The first official mention of gold in the country was made in the official despatch of Sir George Gipps, lieutenant-governor of New South Wales, dated 2nd of September, 1840, in which is included a report from Count Strzelecki, stating that he had discovered a stream of Gwyd, in 1839, a small quantity of gold in an "innerfing-sulphide" which was "undoubtedly deposited." No further notice was taken of this communication. Sir J. E. Murchison, however, in the course of various statements respecting the Urals, which he read to the Geological Society of London, in 1843 and 1844, called the attention of men of science to the fact of the similarity of the formation of the Australian to those of the Urals Mountains, and asserted his belief that gold must exist in Australia. No steps were taken to pursue the inquiry practically, and it was not until 1846 that Sir Roderick addressed a letter to the Geological Society of Cornwall, urging unemploying Cornish miners to emigrate and search for gold in the drift and debris of the Australian Alps. In 1846 Sir Roderick addressed a letter to Earl Grey, the then Secretary of State for the Colonies, who forwarded it to the Governor of New South Wales, and it was subsequently pointed out, as the Sierra Nevada in California. But it was not until 1849 that a Mr. Smith communicated to the governor, Sir C. A. Fitzroy, that he had found gold in a particular place, produced a specimen, and offered to discover the locality by the certain and somewhat later Mr. Lancotlford forwarded a specimen weighing 34 ounces, which he had found in the river Turon, near its junction with the Macquarie, with a similar proposal. The offer was accepted; and on the 1st of April, 1851, when Mr. Hargraves, who had returned from gold-seeking in California, wrote to Governor Fitzroy, announcing that he had been seeking for and had found gold, and offering to discover the localities on being assured of a reward. The offer was accepted, and a bill would meet with a reward, but declined assuring him of any beforehand. Upon this Mr. Hargraves disclosed the places where he had found gold—namely, Lewis Port, Summerhill Creek, the Macquarie River, and another in the districts of
Bathurst and Wellington, about 150 miles west of Sydney. When the government officer was sent in May to examine the claims and the diggings, he found them unproductive. The governor immediately issued a proclamation claiming the gold for the Crown, and forbidding any person to dig for it on his private account. But this was found at once to be quite impracticable, and these restrictions were soon swept away by the governor to grant licences at the rate of 30s. per month. By May 26th there were 1000 persons employed in digging and washing at Summerhill Creek and its neighbourhood, which took the name of Ophir. In July gold was found in two places, first at the colony of Victoria; and from that time the discoveries of fresh localities still richer in gold have been made almost without intermission. On the 3rd of June the governor ordered a reward of £500 to be paid to Mr. Hargraves, who subsequently received a ten-year lease as assistant colonist. During the early part of 1852, a further sum was awarded to him, making his reward in all amount to 5000l. Policemen were appointed to the various stations, and escorts furnished for bringing the gold from the diggings to the ports of Sydney or Melbourne. An assay-office was subsequently established at Adelaide, and a mint has been established at Sydney. The effect of the gold discovery on the colonists was most extraordinary. In a short time the towns and villages were deserted, all the small agricultural traffic was suspended, and every one capable of labour repaired to the diggings, so that serious apprehensions were entertained that the growing crops would be left unattended, the wool of the numerous flocks remain untended, and the flocks themselves be destroyed by disease. But no such evil was vouchsafed; the colonists averted the colonists exerted themselves to obtain assistance, and on the news that gold was to be had for gathering being made known in England, an immigration ensued almost without a parallel. It is estimated that in 1852 not less than from 90,000 to 100,000 persons left England for Sydney and Melbourne, and it was found difficult to provide ships to convey them. The emigration from England during 1853 was on an equally large scale, but has since somewhat diminished. A railroad has been constructed between Adelaide and Port Adelaide, and several of provisions rose greatly, particularly in the diggings, which are usually in remote districts, to which there are no roads; the sheep instead of, as previously, being shorn and their carcasses boiled down for tallow, were driven to the diggings for food, and the wool and skin taken away. The effect on the public revenue is shown in a striking manner by a comparison of that of the colony of Victoria in the first three quarters of 1851 and 1852. In the three quarters ending September, 1851, the revenue was 256,992l. 19s. 3d.; while in the three quarters ending September, 1852, it was 979,476l. 3s. 1d., being an increase of 783,494l. 14s. The revenue of Victoria in 1857 was upwards of 3,000,000l. From the first discovery of gold in Victoria up to 9th February, 1853, the quantity of gold produced by Victoria was estimated by government authorities to have amounted to 6,166,234 ounces, of the estimated value of 19,373,377l. The gold exported from Victoria during the year 1857 amounted to 5,582,798 ounces, valued at 25,393,964l., or about 45 per cent less in value than the total amount of gold paid to the Government. The places where gold has been found now extend from the Grafton range, New South Wales, in 26° S. lat., 149° E. long., to Ballarat in Victoria, 37° S. lat., 144° E. long.; while two small gold fields have been discovered about 37 miles from Adelaide, South Australia, 33° S. lat., 130° 20' E. long. What may be called the main gold region of New South Wales alone, including no portion of the northern district, where gold has been found in considerable quantities, and in which wholly omitting the valuable gold-fields of Victoria, the number of persons employed is estimated by government commissioner, the Rev. W. B. Clarke, after several surveying journeys, to embrace an area of 16,000 square miles; and this he says, in a subsequent report, "is strictly within the limits of South, and very nearly of the whole of the county," which is the district west of the Murray River, and is almost entirely desert excepting several important mountain ranges at no considerable distance." The whole basin of the Murrumbidgee, from near Bellanangam to the junction of the Queanbeyan River, is also said by Mr. Clarke to exhibit "not only metallic formations of the purest and richest kinds, but iron," in conjunction with abundance of limestones: quartz porphyry is here the prevalent rock. And in other districts the metals have been found under equally promising circumstances.

Lead has been found in New South Wales, and worked successfully at Yattagoolinga mines, where the average yield is said to be 75 per cent. of lead and 18 to 20 oz. of silver to the ton of ore; it is also worked at some other mines. In the great mountain ranges of Victoria and New South Wales, lead has also been found in the Darling Range and near Mount Gipps and Mount Stirling. Iron ore abounds on the eastern coast of New South Wales, where also coal is found in large quantities; whence we may conclude that at no very distant period the eastern side of Australia may be studded with iron foundries, distributing their products over Southern Asia and among the numerous islands of the Indian and Pacific oceans. From the discoveries of the mountain ranges and many Warrnangallungu mountains. Argillites and lead ores occur extensively in the regions of the Australian Alps. In South Australia iron-ore is said to abound in the mountains on the East of Spencer and St. Vincent gulfs; at Rapid Bay, Eyre Peninsula, and on the coasts of the Great Australian Rock Hill. No iron works have however, we believe, been yet established.

Native silver has been found in small quantities. Tin has also been found in New South Wales. Blacklead is said to have been found near Adelaide, at Mount Torrens, and in the Belvedere Range, South Australia. Manganese and sulphur are also reported to have been found. Indications of quicksilver have been met with in the vicinity of the Ophir gold-diggings. In the recent explorations of the mountain ranges it has been found that the precious genes exist in many parts of New South Wales, Victoria, and South Australia. The surveyor-general Sir T. L. Mitchell brought with him, on his recent visit to England, a diamond which has been pronounced a diamond by the Royal Society of London. Mr. Stichbury, the government geological surveyor of New South Wales, reports having seen a small but beautifully crystal- lised diamond from the Turon River, and topazes, garnets, rubies, sapphire, and chrysolite, found near Bathurst. The q

in the clay slate formation; the lead runs from east to west. Many other copper and some lead mines have since been opened in the colony, with more or less success. The gold excitement has for a while almost entirely suspended the exploration of mountain regions. The number of careful examinations which have been made of the gold regions, especially those undertaken by the government geological surveyors, have made known the existence of numerous and widely-spread metallic veins, of considerable value, which are now being worked. The gold which has been passed away, lead to most important mining operations. The value of some of these regions may be estimated from the Report of Mr. Clarke to the government respecting a portion of country situated on Oulong near the junction of the Queanbeyan and the Conder with the Delegate River, about 37° S. lat., 149° E. long., near the boundary of New South Wales and Victoria. The district is occupied by sites, traversed by quartz and trap, with occasional patches of granite; but, he says, "what renders this locality so interesting and full of promise is the fact, that in addition to the four metals, gold, iron, lead, and copper, existing in so narrow a compass, there is also abundance of excellent limestones to serve as flux in case of its requirement, and abundance of water in the vicinity, which is absolutely necessary for the preparation of the ores." The lead is reported to vary in quality and quantity in great ranges at no considerable distance. The whole basin of the Murrumbidgee, from near Bellanangam to the junction of the Queanbeyan River, is also said by Mr. Clarke to exhibit "not only metallic formations of the purest and richest kinds, but iron," in conjunction with abundance of limestones: quartz porphyry is here the prevalent rock. And in other districts the metals have been found under equally promising circumstances.

...
Large tracts of limestone occur on the eastern and south-eastern side of the continent; clay flats for the economic purposes of life are common in many places; there are numerous sandstone districts which seem well adapted for ornamental buildings; gypsum is found abundantly in the clay and sandstone districts, and the vicinity of Swan River; and there is roofstone stable in the eastern and western parts of Australia.

Climate.—The climate of Australia differs considerably from that of other countries. The most remarkable as well as the most interesting of its characteristics is the dryness which occasionally prevails. Captain Sturt says:—"The year 1826 commenced the severe droughts to which we have reason to believe the climate of New South Wales is subject. There has been inferior quality during the past year, and with unabated severity. The surface of the earth became so parched that the minor vegetation ceased upon it. Culinary herbs were raised with difficulty, and crops failed even in the most favourable situations. Settlers drove their flocks and herds to distant tracts for pasture and water."

The interior suffered equally with the coast, and men at length began to despair under so alarming a visitation. It almost appeared as if the Australian sky was never again to be traversed by a cloud. These seasons without rain appear to continue for a period of one or two years. They are succeeded by excessively long rains, but afterwards the rains decrease gradually year after year until they again wholly cease for a time.

Another peculiarity is the quick transition from heat to cold. There are instances of the thermometer having varied 25 degrees in 50 minutes. This is owing to the sudden change of the winds. The north-west winds blowing over the great sandy deserts in the interior attain such a degree of heat before they reach the plains and mountains that the thermometer rises suddenly from 80° to 110° in the shade. On the other hand, the south-east winds are often cold and piercing, especially when there is a sudden shift of wind. The thermometer in South Australia often falls 40 degrees in a quarter of an hour.

But in spite of such occurrences, which are to be considered as exceptions, the climate over most of the settled part of the country, though somewhat too dry, is commonly delightful, and the evenings and mornings as pleasant as in southern Italy. Even the great heat which occurs does not produce relaxing and enfeebling effects on the constitution. On the contrary, many stock-keepers, who have been of the country from September to March between 36° and 106°, its mean elevation being 70°; and in winter (from March to September) between 27° and 95°, its mean being 60°.

In the interior and to the west of the mountain ranges the wet season commences from Bathurst to Hunter's River, or has been generally observed in the beginning of the winter. Dews are very frequent and heavy, and sometimes they fall as a drizzling rain. Hall-sprains are common in December and January.

On the low coasts frost is very little felt, but in the hilly districts it is frequent, and very keen on the high terraces on the western side of the mountains, especially on the plains of Bathurst and the plains contiguous to them; these districts are 2000 feet above the sea. It is likewise observed that in these parts of the country the seasons are nearly a month later than on the low district on the coast. The snow lies on the tops of the mountains and occasionally also in the valleys for many days together, but it is absolutely unknown in the plains of Bathurst and the plains of the coast. In his explorations of Tropical Australia, Major Mitchell experienced much frost, the thermometer being on the 24th of June 17° Fahr., or 15 degrees below freezing point. Probably comfort was experienced by any of the party, circumstance which he attributes to the great dryness of the atmosphere.

The climate on the eastern coast is very favourable to health; and endemic diseases are not known with the exception of a few cases of small-pox; they are well known in their employment, and in their occupation; in this latter case the natives have been receiving 204 a year, and the commissioners seem to be agreed in stating, that "both the disposition of the aboriginal native to work, and of the settler to make use of his labour, has been considerably increased by the employment of paying them by a money wage has tended greatly to produce this change in the habits of the native; and as the setters are now fully alive to the fact, there can be no doubt that the practice will be continued." (Report of Mr. Commissioner Merewether.)

The above statement is affirmed very strongly by the cases where the system of money payments has not been adopted, the settlers still find great difficulty in retaining the natives as servants, and complain of their idleness and misconduct. In Victoria the report is much the same, and in South Wales; but in South Australia there seems to be much satisfaction felt at the change in the aborigines. The Protector of the Aborigines in that colony states that upwards
of 900,000 sheep were in June, 1853, under the sole charge of
native shepherds. A training institution for aborigines has been established at Adelaide, chiefly by the exertions of
Archdeacon Hale, who resides on the establishment. He
says that even his "own sanguine expectations did not lead
him to anticipate a speedier result from Native Australia
than that which has attended our efforts, nor so rapid an increase
in the number of our inmates." Besides the school-room,
mess-room, &c., there are 20 huts occupied by native married
couples. There is also a small farm, the work of which,
with herding, is still going on. It is done by the inmates of
the institution, who are also taught brick-making, building,
and other useful occupations. In New South Wales a
"native police corps has been established," which the
Governor-General reports to have been done much in maintaining
order amongst the aborigines. There appears, he adds,
to be no difficulty in recruiting for this force, as
the young men of the different tribes are found anxious to enlist.
Quarterly reports respecting the condition of the aborigines
are made by the district commissioners to the governors
of the several colonies, by whom they are regularly transmitted
to the Secretary of State for the Colonies.

**Divisions, Government, 
&c.—The entire island of Australia**
is a British possession. It is divided by the British govern-
ment into the colonies of New South Wales, Victoria, South
Australia, Western Australia, and the district of North
Australia. New South Wales occupies the south-eastern
portion of the island, extending from the shores of the Pacific
to 141° E. long., and northward to 26° S. lat. Victoria is
separated from the north by this portion of the Pacific, and
from New South Wales by the Murray River, and a line carried from its source
on the Australian Alps in a south-eastern direction to Cape
Howe. Its southern boundary is the Southern Sea; on the
west it is divided from South Australia by the meridian of 141°
E. long. South Australia extends from 141° to 132° E. long.,
and northward to 26° S. lat. Western Australia occupies the
entire country west of 139° E. long. North Australia oc-
cupies the entire country north of 26° S. lat. and east of
139° E. long. The population is chiefly collected about the
south-east coast in the colonies of New South Wales and
Victoria; Western Australia is very thinly peopled. North
Australia is not colonised, the settlement of Port Essington
having been abandoned; on this coast there are consequently
no European inhabitants, but a considerable number of Malay
fishermen have settled upon it. The total population (ex-
clusive of natives and Malays) in 1850 was 335,107, of whom
265,503 belonged to New South Wales and Victoria, 63,700
to South Australia, and 5,904 to Western Australia. It has
since very rapidly increased, owing to the immigration con-
sequent on the gold discoveries.

On August 9th, 1850, an Act of the Imperial Parliament
received the royal assent, by which representative constitu-
tions were given, as distinct colonies, to New South Wales,
Victoria, South Australia, and Western Australia (as well as
to Van Diemen's Land); with power to form other districts
if necessary, and also powers of modification. The details
of the constitutions will be found under the heads of the
several colonies. The governors of Victoria, South Australia,
BAILLIE, JOANNA, was born at the manse at Bothwell, near Glasgow, in 1762. She was the sister of Dr. Matthew Baille. The history of her uneventful life is soon told. The daughter of a man of the parish of Divinity, and of a mother in whose family superior intelligence seemed a common property, Joanna, while trained in the strictest manner usual in a Scottish manse, not only received an excellent education, but from her childhood was brought into constant intercourse with people likely to call into action her own mental gifts. Her career through life was quiet, unobtrusive, domestic; her tastes were all studious; her disposition was gentle, kindly, and unobtrusive. At an early period she removed to London, where her brother, Dr. Baille, was settled as a physician. After a time, she, with her sister Agnes, took up her residence at Hampstead, which, while from its proximity to the metropolis it allowed her to enjoy ready intercourse with the many friends her literary fame drew about her, insured her at the same time a certain amount of retirement; and here the rest of her lengthened life was spent. She was known and esteemed by the most eminent of her contemporaries of more than two generations, and for very many years, even from the New World, visitors, attracted by her friendly nature and her capacity for making acquaintance and to listen to her conversation. Those who visited her out of admiration returned adding to that sentiment feelings of affection and respect. She died at Hampstead on the 22nd of February, 1811, in her 89th year, having retained her faculties to the last.

Though Joanna Baille possessed in a large measure that keen and sensitive instinct in all that developed the feelings or touched the destinies of others, and that sensibility and sympathy which predispose for the golden path of moral excellence, yet these sentiments had in her instance more of perverseness and of speculative character than of fire, and made her seek and find events in her own thoughts rather than in action and experiment. Adventure may be, and has often been, the school of poetry for men; but a woman, and especially one of Joanna Baille's feminine and modest disposition, must invoke the muse with a serener and more gentle worship. A close and penetrating observer, and gifted with no common genius, but not favoured with the highest, nor weakened with the inspiration of 'many-mindedness,' which makes poetry of the first order bear to philosophy the same relation that intuition bears to calculation, Joanna Baille early in life conceived a literary project based on the discovery of her talents. With the permission of her greatest works, the celebrated 'Plays on the Passions.' The principle on which all these plays were constructed was to select some one of the more powerful passions that agitate mankind, and to exhibit it in full action, by making the hero of the drama completely subjected to it, and by evolving out of the promptings to which he is represented as paying undivided and uninterrupted allegiance, every incident and situation. Admitting fully the noble poetry with which these plays are filled, and even the deep interest of many positions and events, it is evident that such characters must have a constrained, morbid, and unreal aspect; since in life, as in the dramatic creations of the highest genius, we constantly see that the dominant passion is turned aside or suspended by, it may be transient, but for the time irresistible, counter-thoughts or the force of circumstances; and this is a main reason why her plays have only achieved a partial and temporary success on the stage. Yet the one moral position often allowed by commentators in her most secret workings—subjected to a keen and searching analysis.

It was in 1798 that Miss Baillie published the first volume of her 'Plays on the Passions.' She was then thirty-six years old, and a second edition was called for in a few months. In 1802 she published a second volume. Two years later, appeared her 'Miscellaneous Plays.' Among these were the 'Family Legend,' a tragedy, which she used to term her 'Highland play.' It was acted for the first time at Edin-
but not sudden improvements he gradually increased its circulation, and extended its influence, while his good taste and temper led him to abjure all grossness and bitterness of altercation.

In 1857 he again opposed Lord John Russell's scheme for state education of the poor, and the opposition of the dissenters was so strong that the plan was withdrawn. On August 8, 1858, he was taken ill, and after a short illness, he died, and was honoured by a public funeral.

BALBI, ADRIEN, was born at Venice, April 22, 1782. At an early period of his life he was appointed professor of Arabic and Persian at the University of Padua. At large at the influence he acquired arose from his being among the first who introduced 'leaders' or original editorial dissertations on political subjects into a provincial paper; these leaders being distinguished by the moderation of their tone, their independence of the authority of others, and the force of their style, and their general good sense. In the severely contested election for Yorkshire in 1807, he took an energetic part in support of Lord Milton in opposition to Mr. Lascelles, although he differed in opinion from Lord Milton-townsmen chose him for alderman as a mark of their respect, but he immediately resigned the office. In 1847 he again opposed Lord John Russell's scheme for state education of the poor, and the opposition of the dissenters was so strong that the plan was withdrawn. On August 8, 1858, he was taken ill, and after a short illness, he died, and was honoured by a public funeral.

tural produce. There is a very productive salmon fishery.
A fever hospital and a dispensary are in the town. Ballylome has a number ofQUALITY andpetty sessions are held; there are fairs on May 13th and August 19th.
The surrounding scenery is remarkably fine, having a fertile and extensive plain towards the sea, bounded on the south and east by the range of the Ox Mountains, and on the west by Nepkin Mountain (2640 feet), and the highlands of Erris. Ten miles north-east of Ballyna, near the shore of Killala Bay, is the ruined castle of Leasan, now called Castle Forbes, remarkable as having been the patrimony of the Forbes family. It contains hereditary scribes and historians of the ancient Irish territory of Hy-Fiachra.

(Travels and Customs of Hy-Fiachra. Published by the Irish Archeological Society, Dublin, 1844; Thom's Irish Almanac.)

BALLINROBE, county of Mayo, Ireland, a market and post-town, and the seat of a Poor-Law Union, in the parish of Ballinrobe, and barony of Kilmaine, is situated on the Bove River, 2 miles from its estuary in Lough Mask, in 53° 37' N. lat., 9° 6' W. long.; distant 141 miles N.W. by W. from Dublin, and 4 miles S.W. from Hollymount on the leading road from Tuam to Castlebar. The population in 1841 was 2078; in 1861 it was 1912, exclusive of 350 inmates of the Union workhouse. In 1851, the county contained 16 electoral divisions, with an area of 144,886 acres, and a population in 1841 of 83,113, in 1851 of 72,856.

Ballinrobe is picturesquely situated chiefly on the left bank of the river Bove, and has on the whole a clean and neat appearance. It is separated from its former importance. In the town are the parish church, a large chapel for Roman Catholics, a chapel for Protestant Dissenters, a market-house, a dispensary, a bridewell, and in the town is a barracks station and a station of the county constabulary force. A market for agricultural produce is held weekly, and fairs on Whit Monday and December 9th.

BALLYOTA, a genus of plants belonging to the natural order Orchidaceae, of which there are several species, among which the most common and most useful is B. fœtida and its variety B. ruditîs. B. fœtida is the most common plant, and goes by the name of Horse- storn. The White Horse-horn is the Marrubium vulgare.

BALLYMENA, county of Antrim, Ireland, a market and post-town, and the seat of a Poor-Law Union, in the parish of Kirkkinsiela and barony of Lower Toome (with the suburb of Harryville in the parish of Ballyclug and barony of Lower Antrim), is situated on the right bank of the Braid River, 2 miles from its estuary into the Lagan. It is the most ancient town in the county, and its inhabitant numberless. In 1841 it was 5949; in 1861 it was 6316, besides 857 in the Union workhouse. Ballymena Poor-law Union contains 23 electoral divisions, with an area of 160,653 acres, and a population in 1841 of 74,159, in 1851 of 71,123.

Ballymena stands in the midst of a very densely-populated district, extending from the neighbouring town of Broughshane on the east to the river Bann on the west. The population here unites the manufacture of linen with the pursuits of agriculture, Ballymena which is their chief market possesses a very considerable and flourishing trade both in linen and agricultural produce. The town is built of stone, and has a respectable appearance. There are any two Roman Catholic, a Wesleyan Methodist, and three Presbyterian places of worship; a market-house with a spire, the Union workhouse; a dispensary, and a bridewell. Quarter and petty sessions are held, and the town is the head quarters of the county constabulary. Saturday is the market day. Fairs are held on July 26th and October 21st. In the vicinity are extensive bleach-grounds. The surrounding district, although divided into very small holdings, is cultivated to the utmost, and presents a rich and pleasing landscape.

BALLYMONEY, county of Antrim, Ireland, a market and post-town, and the seat of a Poor-Law Union, in the parish of Ballymoney and barony of Upper Dunlusk, is situated on the leading road from Belfast to Londonderry, 3 miles E. of the river Bann, in 50° 4' N. lat., 5° 31' W. long., 18 miles N.W. by N. from Ballymena, 84 miles S.E. from Coleraine, and 146 miles N.W. from Dublin. The population in 1841 was 2393; in 1851 it was 2681, exclusive of 373 in the Union workhouse. It contains 33 electoral divisions, with an area of 187,115 acres, and a population in 1841 of 60,710, in 1851 of 62,418. The town is irregularly built on a small stream which runs into the Bann, near the church of the Establishment, a chapel for Roman Catholics, several churches, a town-hall, a dispensary, the Union workhouse, and a bride walk. Quarter and petty sessions are held, and there are here stations of the constabulary and the revenue police. Ballymoney has a small trade in linens and dairy produce is held monthly, and fairs are held on May 6th, July 10th and October 10th.

BALM. [Callimorphis, S. 1; Melithena, S. 1]

BALSAM, [Callimorphis, S. 1; Melithena, S. 1]

BALZAC, HONORE DE, a French novelist, was born at Tours, May 20, 1799. He was the son of a clerk under the government of Louis XV. At the college of Vendôme, where young Balzac was sent early, he gained the character of an idle and indolent student, and was removed to a private academy. On leaving school he was placed with a notary in Paris, but he almost immediately commenced writing articles for the journals. These are said to be rather testimonies of his perseverance than monuments of his genius. About this time he had published 'Contes du dimanche,' none of them exciting or deserving much attention, under the assumed name of Horace de St-Anbin. In 1825, in connection with one Barbey, he commenced business as a printer and bookseller, and among other things published an edition of Fontenelle's 'Monuments,' written by himself, and commenced the 'Annales Romantiques.' His speculation was altogether unsuccessful. In 1829 he appeared before the public for the first time, under his own name, with 'Le Père Goriot.'

It was not however till the publication of his 'Peau de Chagrin,' in 1839, under his own name, that the Parisian world became acquainted with the genius that distinguished his works. From that period he was a general favourite in France, and many of his productions have been translated into most of the languages of Europe. He was indefatigable in supplying the public craving under the title of 'Comédie Humaine.' He planned a series of compositions that was to embrance every phase of human society; and at this he worked for twenty years. Among the most popular were 'Le Fils de l'Amour,' and 'Le Père Goriot.'

On the publication of the 'Médecin de Campagne,' in 1836, Balzac received a complimentary letter from the Countess Eveline de Hanse, the wife of a Polish nobleman, possessing large estates in Russian Poland. Balzac replied, and an acquaintance was thus formed. In 1838 he selected and translated into French his novel of 'Sersaphia' was dedicated. The countess became a widow, and a few months after the revolution of February 1848 Balzac quitted Paris to bring her back as his wife. He inhabited a large house in the hotel Montmorency, and conducted a number of people under his influence, and in which he hoped to find happiness and peace. But even before his journey he had been attacked by a disorder which it was found impossible to cure or to postpone—illness of the heart—of which he died, August 20, 1850. He was buried in the cemetery of Père-la-Chaise, an immense crowd attending the funeral; and Victor Hugo pronounced a critical oration over his grave. In that eulogy, he says, Balzac 'chastised vice, disected passion, fathom'd and surround'm man's heart, his feelings, his sphere in the abyss of each in its very essence.' There is more asserted here than an English reader can concur in. Balzac had a rich fancy, but not a pure taste; he was an acute observer, but often overambitious, sometimes extravagant, and sometimes wearisome. His 'Contes Drolastiques'—thirty short tales—are written in an antiquated form, a sort of resemblance to the 'Hepameron Francois' of Margaret of Navarre. The 'Contes Phintiques et Romantiques' are the tales of M. de Balzac and the others of Voltaire, of which they are in some degree imitations. His dramas, of which he wrote a few, were failures.

(Nouvelle Biographie Générale.)

BANAGHER, King's County, Ireland, a post-town in the parish of Ballygarry and barony of Garrycastle, is situated in 53° 19' N. lat., 7° 54' W. long., on the left bank of the river H
Shannon, which is here crossed by a bridge leading to Galway by way of Eyrecourt; distant 24 miles S.S.W. from Shannon harbour, where the river is connected by the Grand Canal with Ballinasloe on the west, and Dublin on the east, and 83 miles W.S.W. from Dublin by the high road. The population in 1841 was 2227. In 1846, the town was built on the intersection of the Brr and Eyrecourt road with that leading from Shannon harbour to Limerick. The old bridge of 18 arches was removed in 1843, and a new bridge of 6 arches of 60 feet span each, with a width of 45 feet, was erected in its stead by the Irish Board of Works. At the eastern end of the bridge is a barric and a magazine, and there are batteries which command the bridge and its approaches on both sides of the river, and which are chiefly in the hands of the Military. Prior to the Union, Banagher was a corporate town, and returned two members to the Irish Parliament. Petty sessions are held here. Fairs are held on May 1st, September 16th, October 28th, and November 8th. The adjoining district is flat, and in the immediate vicinity of great tracts of bog, but it is well cultivated.

BANBRIDGE, county of Down, Ireland, a post-town and the seat of a Poor-Law Union, is situated on the left bank of the river Bann, on the leading road from Newry to Belfast, in 54° 20' N. lat., 6° 16' W. long, 13 miles N. by E. from Newry, and 76 miles N. from Dublin. The population in 1841 was 3524, in 1851 it was 5501, exclusive of 478 inmates of the Union. The Banbridge Union comprises 23 electoral divisions, with an area of 194,992 acres, and a population in 1841 of 87,100, in 1851 of 74,844.

The principal part of the town is built upon an eminence, having a steep declivity towards the river. To obviate this inconvenience, a causeway of the width sufficient to admit of the alteration, was lowered to a depth of fifteen feet, leaving elevated causeways on each side. In carrying this arrangement into effect, it was necessary to remove the old market house which was formerly stood in the middle of the street on the summit of the hill: a viaduct connecting the opposite terraces now occupies the site. The town consists chiefly of this main street, and is substantially and neatly built, but has no building of pretension except the new market and centre of the main street. The church is pleasantly situated on a level green adjoining the bridge, on the right bank of the river. The Wesleyan Methodists have one chapel, and the Presbyterians have three chapels. Petty sessions are held here, and there is a station of the constabulary force. Twelve fairs are held in the course of the year.

The linen trade in all its branches is carried on with great activity in the immediate neighborhood. The line of the Bann, from a distance of several miles above the town to the mouth, is covered with an almost continuous succession of bleach-greens. At Huntley Glen, a little below the town, is a large thread-spinning factory; and at Seapatrick an extensive establishment for weaving union cloth by machinery. A bridge has stood at this point of the Bann from a very early date. John Barham, A.D. 1210, the place is mentioned under its present name.

(Fraser, Handbook for Ireland; Original Communications.)

BAND-FISH. [Carpola.]

BANKRUPTCY. The numerous statutes relating to bankruptcy have been consolidated by the Bankrupt Law Consolidation Act, 1849, which has been amended in one or two particulars by the statute 17 & 18 Vict. c. 119. The classes of persons who are declared bankrupts are the persons whose creditors are unpaid, and extended, and the proceedings in court simplified. They are commenced by a petition either by the trader himself, or by a creditor or creditors; upon which an adjudication is made, and after notice, a petition is presented to the Lords Justices of the Court of Appeal in Chancery, who are in place of the judges of the Court of Chancery, and upon the judgment of the court is brought in the name of the bankrupt in the mean time vested by the adjudication in an official assignee; and on a choice being made by the creditors, in him and their assignees jointly, the control of the Court being exercised throughout on the collection and distribution of the estate. Contributions, in the shape of Bankruptcy (7 & 8 Vict. c. 111), insurance companies, and banking companies of more than seven partners (7 & 8 Vict. c. 113), may be made bankrupt. Joint Stock Companies, with limited liability, are wound up, when necessary, in the Courts of Bankruptcy; and the Court of Chancery may send the winding-up of companies, whose liability is unlimited, to this tribunal (19 & 20 Vict. c. 47; 20 & 21 Vict. c. 14). Blackst., Comm., Mr. Kerr's ed., v. ii. p. 494. See also Insolvency.

The bankrupt laws of Scotland have been consolidated to some extent, and the procedure in a sequestration simplified and cheapened by the statute 19 & 20 Vict. c. 79.

The Statute 18 & 19 Vict. c. 59, which aggrandized the laws relating to bankrupts and insolvents in that part of the kingdom have been consolidated, and the administration thereof committed to a new court called 'The Court of Bankruptcy and Insolvency' (20 & 21 Vict. c. 60).

BARKER, BARBARA.

BARBERRY BLEIGHT. [Jacobite.]

BARBUS, [Barbel.]

BARHAM, REV. RICHARD HARRIS, was born December 6, 1786, at Canterbury, where his family had resided for many generations. He was an only son, and his father, who died in 1793, left him a small estate. In 1808 his right arm was severely shotted by the upsetting of the Dover mail, in which he was travelling to St. Paul's School, London. His life was despaired of for some time, but he ultimately recovered, and regained the use of his arm. From St. Paul's School he was removed to Brasenose College, Oxford, where, during a short but severe illness, he first entertained the thought of entering into the church, though he had previously been inclined to enter the army. He afterwards became a student in the church, and was ordained for the cure of one of the places in the city of Gloucester, and was afterwards admitted to a small pension at Truro, as a candidate for a vacant minor's way. He was, in 1821, ordained a deacon, and in 1824, a priest; and was presented to the living of St. Michael's, Glastonbury, by the Archbishop of Canterbury to the rectory of Snargate, and he obtained at the same time the cure of Warham, the former in Romney Marsh, Kent, a district much frequented by smugglers, and the income of it was very much in reality a duty of State. As the church was absolutely unknown to him, he had no chance of success, he was only elected in 1821. He thenceforth devoted much of the time not required by his professional duties to contributions in verse and verse to the periodical publications of the day. His 'My Cousin Nicholas' in 'Blackwood's Magazine,' and about one-third of the articles in Gorton's 'Biographical Dictionary' were written by him. 'My Cousin Nicholas' has since been published in a separate form.

In 1824 Mr. Barham received the appointment of a priest in the ordinary of the Chapel Royal, and shortly afterwards was presented to the rectory of the united parishes of St. Mary Magdalene and St. Gregory by St. Paul's, London.

The 'Miscellany of the University of Oxford' published in 1824 by the Rev. Theodor Hook, the Rev. Sydney Smith, and several other of the distinguished wits of his day, and was, like them, a frequent dinner-entertainer, a sayer of good things, and a teller of droll stories; but his writings are not now dwelt on, and were much respected by those who knew him.

The 'Ingoldsby Legends' have been published in 3 vols., post 8vo. 'A Memoir of the Rev. Richard Harris Barham,' by his son the Rev. R. H. D. Barham, precedes the Third Edition.

BARKER, THOMAS, was born near Pontypool, Monmouthshire, in 1769. His father was by profession a barrister, but being a man of desultory and expensive habits,
George Staunton, to whose son he had given lessons in mathematics, the appointment nominally of comptroller of the household to the Emperor of China; but really to take charge of the various philosophical instruments carried out as presents to the emperor of China. Of this journey he published an account some ten years later in a thick quarto volume entitled "Travels in China." In this embassy Mr. Barrow secured a present of Lord Macartney, that his lordship made him his private secretary on being appointed Governor of the Cape of Good Hope in 1797; and when Lord Macartney quitted the Cape in 1798 he left Mr. Barrow in the post of auditor-general of public accounts. During his stay at the Cape Mr. Barrow devoted his leisure hours to the study of the geography and natural history of South Africa, and made several journeys into the interior. On his return to England he published theictures of his travels in the "History of the British Empire in Various Parts of the World," the "History of the Cape of Good Hope," and the "Travels in Southern Africa." In 1804 Mr. Barrow was appointed by Lord Melville to the responsible post of second Secretary to the Admiralty, the duties of which he continued to discharge for a period of forty years under thirteen administration.

In this office Mr. Barrow was earnest and indefatigable in the promotion of every project which commended itself to his judgment as calculated to advance the progress of geographical or scientific knowledge. Especially did he aid in the extension of the British possession of the Cape of Good Hope by various governments under which he served, and to the country, the prosecution of the various voyages to the Arctic Regions which have so characterised the naval history of England during the last forty years of his connection with the Admiralty; and through his services he was commemorated by associating his name with the point of land, Cape Barrow, yet such was the sense entertained of them by those officers who had been engaged in those voyages, that, on his retirement from the post of auditor-general of public accounts, he was given a costly candelabrum, bearing a suitable inscription on the pedestal.

Mr. Barrow was a man of untried industry. The leisure hours afforded by his official employment were devoted to the cultivation of every science and art; and, though his writings in the above-mentioned branch of literature and science circles of the metropolis. He was for a long period a member of most of the leading learned societies of London. In 1808 he was elected a Fellow of the Royal Society; in 1830 he took a leading part in the foundation of the Geographical Society of London, of which some years later he was chosen president. In 1838 he was created a baronet.

In the beginning of 1845 Sir John Barrow, then in his eighty-first year, resigned his office at the Admiralty, and retired from public life. He had as early as 1806 received the interest of a considerable pension of 1000L. per annum, to be deducted from the emoluments of any place he might hold under government. He died almost suddenly on the 23rd of November, 1845, in the eighty-fourth year of his age. Besides the works mentioned above, Sir John Barrow published a "Life of Earl Macartney;" "Life of George Lord Anson;" "Life of Lord Howe;" "Life of Drake;" "Memoirs of Naval Worthies of Queen Elizabeth's Reign;" "Chronological History of Arctic Voyages;" "Voyages of Discovery and Research within the Arctic Regions;" "Sketches of Royal Society and Royal Society Club;" the "Life of Peter the Great;" and the " MUTINY of the Bounty" in the "Family Library;" and his "Autobiographical Memoir," written in his eighty-first year, was esteemed a valuable contribution to the "Quarterly Review," having in all furnished 195 articles to that journal, and he wrote some papers for the "Encyclopedia Britannica," as well as for one or two other periodical publications.

(An Autobiographical Memoir of Sir John Barrow, Bart.; Sir G. T. Staunton, Memoir of Sir John Barrow, edited by J. B. (John Barrow, son of the above article)]

BARREY, MARTIN, an eminent physiologist, was born at Fratron, Hampshire, July 25, 1824. He early manifested for scientific pursuits, led his parents to give up their scheme of a mercantile life for their son, and he studied in the universities of Edinburgh, Paris, Berlin, and other places of Europe and America, and resided for some years in London. He entered warmly into the proceedings of the societies of the Scottish metropolis, and spent most of his...
holidays in geological and botanical excursions on foot among the lakes and mountains. He took his degree of M.D. at Edinburgh in 1833, and in the following year, after a term of study at Heidelberg, he rambled through Switzerland and Chamouni, where, though past the middle of September, too late in the season, as was thought, for success, he went to the mountains and performed many ascensions of the great summits; and Humboldt was so pleased with the narrative of the adventure published by Barry in 1836, that he personally requested him to translate his 'Two Attempts to ascend Chimborazo in Ecuador.'

Martin Barry has the merit of being one of the few physiologists who devoted their attention to the difficult question of animal development and embryology. He began by making himself well acquainted with the literature of the subject, and his friendship with Purkinje, Valentin, and Schwann, brought his knowledge to the test of observation, and acquired that mastery over the microscope which afterwards appeared in the importance and value of his researches.

Having published in the 'Edinburgh Medical and Surgical Journal' for 1836, a translation of the first part of Valentín's 'Manual of the History of Development,' he commenced his investigations into the development of the mammalian ovum and the formation of the blastoderm. "This part of embryological science," he noted, "the results, communicated to the Royal Society of London, were printed in the 'Philosophical Transactions' under the general title of 'Researches in Embryology.' These, as well as his papers 'On the Corpuscles of the Ovary'; 'On the Fetal Membrane'; 'On Fibre,' &c., will be found in the 'Philosophical Transactions' from 1838 to 1842. The most important—the discovery by which he will be best remembered—'Spermatozon found in the blood of a man.' The Royal Society recognized the value of Barry's researches by awarding him his royal medal in 1839, and electing him a Fellow in the following year.

The 'Researches in Embryology' exhibit proofs of the author's skill in the grouping and selection of his facts, and of the perseverance by which they were demonstrated. He explains the formation of the ovum in the rabbit and dog, and in some of the oviparous vertebrate classes from the bird to the fish. He determined the order of formation of different parts of the ovum, and the nature and modes of its growth from the ovicle; and showed that the so-called 'disc of Von Baer' contained a retinacula, or peculiar species of mechanism, by which, as he supposed, the passage of the ovum into the Fallopian tube was regulated. He described the changes that take place in the ovum while on its passage—changes before unknown; and Barry was the first to throw light on this interesting process of animal development. Not till his paper appeared in 1839, was it known that the yolk of the bird had been observed in Batracian reptiles, and true of mammals. It was an important discovery; and not less so that published in 1840—the penetration of the ovum of the rabbit by spermatozoa, through an aperture in the zona pellucida. This at first was doubted; but he confirmed it by further observation in 1843; and it was eventually corroborated by the observations of Nelson and Newport, accounts of which are also published in the 'Philosophical Transactions;' and Professor Bischoff, who had denied the truth of Barry's conclusions, was at last satisfied himself of their accuracy, and accepted them in full.

The views expressed by Barry in his paper 'On Fibre,' are disputed by physiologists. He assumed a spiral structure for the ovum and other organs, and went on to speculative arguments to bear in favour of his opinions; but other investigations show one and the other to be fallacious. His speculations have however tended to stimulate physiological research. Whatever may have been Barry's feeling for his own favourite ideas, his character as an amiable and benevolent man is beyond question. Ample private circumstances placed him above the need of practising his profession; and he devoted much of his time to the poor, chiefly as a house-surgeon and medical officer of the Charity Maternity Hospital in Edinburgh. From 1840 to 1853 he lived on the Continent to recruit his health and eyesight, both having suffered from long and severe study. At Prague he renewed his examinations in anatomy only with Purkinje; with what result may be seen in Müller's 'Anatomy,' 1860. In 1853 he returned to Scotland, suffering much from neuralgia; and having gone to reside at Eccles, in Suffolk, he died there on the 27th of April, 1856. He was a member of the Society of Experts.

Barry was a member of the Royal Society of Edinburgh, of the Wernerian and other societies, and the College of Surgeons in that city. Some of his papers and translations are printed in the Edinburgh or Philosophical Journal; and several of his works were included in the periodicals already mentioned.

BARTON, BERNARD, was born in London in 1784. His parents were members of the Society of Friends, and to the tenets of that sect Bernard Barton always adhered. In 1803 he matriculated at Christ Church, Oxford, at which he entered as a clerk the banking-house of Messrs. Alexander, in whose employment he continued almost to his death. Bernard Barton first claimed public attention as a poet in 1812, by the publication of a volume of 'Metrical Effusions.' This was followed by a volume of 'The Works of William Shakespeare,' published in 1819. Thenceforward as long as he lived he continued to issue at intervals either brief occasional pieces, or, though much more rarely, a poem of greater length and loftier pretensions.

Barry exhibited an amount of scientific and popular facility far beyond that to which his poetic merits would seem to have entitled him. This was perhaps mainly owing to his presenting the then unusual phenomena of a Quaker poet—the title indeed by which he came to be commonly transcribed in his poems, which in the evidently unaffected tone of simple religious earnestness which pervades all his writings, he wrote with ease; and like most easily written poetry, his verses are more characterised by fluency than power. But though often diluted almost beyond recognition by the Chrysalis of Wordsworth's unobtrusive benevolence running through his verses, which render them pleasing to all but the more critical class of readers. Barton was a man of refined habits; a lover of nature, and an advocate of institutions for the advancement of a degree of general education in a very uncommon manner among members of his sect.

His moral character was blameless, and few men in his position of life won so wide and general a share of esteem as did Bernard Barton. Some years before his death he was presented by the University of Edinburgh, with the grant of a pension of 1000l. per annum. He died suddenly on the 1st of February, 1849. Besides the works noticed above, Barton published 'Napoleon and other Poems,' 1822; 'Poetical Vignets,' 1824; 'Devotional Verses,' 1826; 'Household Verses,' 'New Year's Eve,' and numerous occasional verses and poems published separately, and in magazines, annuals, &c.

(Memoir, prefixed to his Poems; Gentleman's Magazine, 1849.)

BASEVI, GEORGE, an eminent architect, was born at Brighton, in 1794. He was placed as a pupil with Sir John Soane, R.A., in whose office he remained for six years. He then made a professional tour through Italy and Greece for three years. His first important work was the design for the high street, another of his latest works, executed by him in conjunction with Mr. Sidney Smirke, it shows that he was rapidly throwing off the trammels of precedent, and giving his fine taste and attainments fuller and freer play. But his manner was neither too broad nor too limited, and the effects unpretending and forcible. Whilst examining, in company with the Dean of Ely, the works in the Bell Tower of Ely Cathedral, the restoration of which was being conducted under his direction, his foot caught in a long stairway which had been removed, and he fell through an aperture on to the top of the arch under the tower, a distance of 40 feet. He died almost instantly, October 16, 1845, aged 51. The Fitzwilliam Museum was finished under the direction of Mr. Cockerell. Basevi's works are numerous.

BASTIAT, FREDERIC, was born at Bayonne, June 29, 1801. He was the son of a marchand, by whom he was
This was reserved for our own day to establish public baths and laundries for the community generally, and for the poorer portion of it in particular. The practical philanthropist early saw that the sanitary improvement of the condition of the poor was a condition of poor health, and he was thus demanding a right to cleanliness, a crusade calling for accomplishment. Medical men, clergymen, city ministers, parochial officers, and all whom either professional duty or benevolence had led to enter the dwellings of the very poor, however their opinion differed in other respects, were at least unanimously agreed that there was a degree of dirt and squalor with which health and morality were alike incompatible. Many remedies for the evil were suggested, and several carried into execution. One little knot of practical men resolved fortunately to give their special attention to the matter of personal cleanliness. It had been allowed by all who were really acquainted with the homes of the very poor, that in their crowded and wretched dwellings and cleanliness was impossible. In such places not only were there the rubbish from personal cleanliness, but to wash and dry clothes properly was quite impracticable. It was proposed, therefore, to see whether the establishment of places where, for a small charge, a warm bath could at any time be had, and where all the conveniences of a family wash were provided, was to meet with popular acceptance. Whether it was or not, a few trials were made. For a trilling cost per hour, would not be gladly accepted by the classes most requiring such conveniences.

The movement was practically initiated by the holding of an influential meeting at the Mansion House, under the presidency of B. B. Cobden, M.P, and resolutions were passed for the formation of an 'Association for Promoting Cleanliness amongst the Poor;' and an active subscription was commenced. The first experiment was made in a wretched locality near the London Docks, where, in an open court, called Glasshouse Yard, Rosemary Lane, an old but spacious building, which had for some time been occupied by sleeping-baths for the homeless poor, was rented and converted into the first 'Free Baths and Wash-houses,' opened in the month of September 1844. A public notice was then adapted, as it could be at a small expense, to the purpose, and furnished with a due supply of tubs and boilers, and with a few baths in various out-of-the-way recesses; and soap and soda, as well as hot and cold water, were provided gratuitously. The number of persons who used the baths increased from day to day, and the success of the establishment was, in the first year, 27,662 bathers and 1,077 washers; in the second year there were 34,584 bathers and washers. This, though the first establishment was not the very small one having been previously started, and with much success, in Liverpool, though without the knowledge of the London Committee. The Glasshouse Yard establishment owed its success solely to its usefulness. There was a strong desire among the ratepayers of the metropolis for one of the worst spots in the metropolis; the building itself was as little united to the purpose as any building well could it; the accommodation was of the most ordinary kind. Yet it at once proved—if proof were needed—that the poorest in that wretched neighborhood would gladly be clean when the means were attainable. In August 1846, a second, and much superior establishment, was opened in George Street, Enston Square; a plot of ground having been liberally purchased by the New River Company, near one of the few reservoirs, with the additional advantage of a free supply of water for the first six months. In the first year there were here some 133,000 bathers and 20,000 washers. This establishment, in which the baths are more varied in price than elsewhere, was still more successful.

The establishment third in point of date was, however, the first in importance and in the value of the consequences which resulted from it. In this the committee first fairly developed their labours. This was, the establishment of the Glasshouse Yard was opened gratuitously, it had been desired that the institution should as soon as practicable be rendered self-supporting by means of a small charge to each person who used it. The committee hoped too, to see the system extended through the kingdom, and 'at a very little cost,' that nothing would so effectually and speedily further that object as to be able to show a Model Establishment, which, while it contained all the conveniences and appliances which those who availed themselves of it could desire, should be in itself all that science, combined with practical skill, could
effect in the economy, suitableness, and completeness of its arrangements. Accordingly, architects and others were invited to send in designs for baths and wash-houses, and a great number of them. The information which could be obtained was collected. The Model Establishment was then erected on a site which had been purchased in Goulston Square, Whitechapel, a very poor and crowded neighbourhood, but of ready access. The building is a magnificent edifice almost entirely novel caused a very large original outlay, and many changes have been subsequently made; but as a whole they had been so carefully considered, and were so judiciously designed by Mr. Prichard Baly, the committee's engineer, that no material alterations had been required. In the present Annual Report of the Committee, we are told that "the general arrangements and mode of construction have been almost universally followed in London and the country." When the character, then, these establishments are pretty much alike. The exterior is usually a plain brick building, with stone quoins and dressings; having a basement, and, in front, a story above it, with a lofty square ventilating and chimney-shaft, somewhat like a campanille in appearance. A brief sketch of the interior of any one will serve to give a general conception of its aim, being understood that there are differences of detail in each.

The baths for males and females are on opposite sides of the building, and separated in Goulston Square by the wash-houses in the offices by the plate-glass window. In both sides are first and second class baths. The apartment in which these are placed is spacious and lofty, covered by an open roof, and lighted in the day by ample skylights, by gas-light at night. The wash-room is usually somewhat more than six square feet, shingled with glass doors, and arranged to carry the height of some ten feet; but the top is open, so as, while insuring privacy, to admit of thorough ventilation. The bath, in some establishments sunk in the ground, in others placed as usual above ground is either of iron enamelled, or of zinc. The first and second class rooms are usually alike in every respect, except that the fittings in the first-class rooms are of a superior kind, and more usually the floor is of the first-class, the door is a door with a key, having a number painted on it; a similar number is painted inside. An index outside enables an attendant to let in either hot or cold water, as the bather may direct. The charge for a first-class warm bath is sixpence, for which two towels, flesh and hair brushes, and a comb are allowed. For a second-class bath the charge is only twopence, but only one towel is allowed, and the bather must provide his own comb and brushes. The baths are in all about the same quantity of water (in most places forty-five gallons, but at St. Martin's much larger), and the bath is invariably cleaned after each person. The most perfect cleanliness is indeed observed in every respect. For a cold bath the charges are respectively threepence for a first-class, twopence for a second-class, and one penny for the regulation cold bath. The baths on the female side are similar to the others, but there is a little more taste in the first-class fittings. At Goulston Square there are only warm and cold baths. At St. Martin's a shower-bath is added. At George Street there are also vapour-baths; and at the more recently constructed establishments there are plunge or swimming baths filled with tepid water. For these swimming-baths the charge is usually twopence for the first, and twopence each person for the second-class. At the larger of the recent establishments there are two swimming-haths—a first and a second class; the smaller places have only one large bath, using it three days a week as a first, and the other three days as a second-class bath.

The baths have everywhere proved exceedingly popular. The second-class baths are, in the summer particularly, always well attended, and of an evening there are generally many waiting for their turns, which are always strictly in the order of arrival.

The number of baths varies, of course, according to the requirements of the locality, and the size of the building. The number of first-class baths, for example, at St. Martin's-in-the-Fields is, twenty-four men's, five women's; of second-class thirty-two and twelve, respectively. At Goulston Square, there are ninety-four first and second class baths. At St. James's, Marshall Street, there are only about fifty of both classes; but there is a swimming-bath. The number of baths in London is over 1,500,000; at St. Martin's-in-the-Fields the number is above 200,000.

The Wash-houses are more remarkable than the bathing-rooms, because entirely unlike what is seen anywhere else. Along the centre, on one side, and at the ends of a large and handsome passage, the soaps, sponges, towels, and other necessaries, the walls being of unpainted slate, and some six or eight feet high; these are the washing-places. At convenient points are the wringing-machines. Along one side of the room (at Goulston Square) is what looks like a range of wide horizontal planks, and have been prepared, to arrange them being one above the other—that is the drying apparatus. A long flannel-covered board is furnished for ironing on. In some of the latest wash-houses a mangle is provided.

Each washing compartment is six feet long by three and a half feet wide by two and a half feet high; the door of each is sunk to the top when the clothes are put in, it is set in rapid motion by a handle which works a few connecting wheels; the clothes at once by centrifugal force arrange themselves around the sides, the water entering by the bottom. The result is that the clothes are carried off by water-pipes: an opening at the foot of the machine shows when the water ceases to flow, and when consequently the 'wringing' is completed, and then the pressure of a lever at once stops the machine. The machine has a rather a heavy-looking frame to it; it is really very light work, and by it three minutes suffice to rid even a thick blanket of its moisture. The Drying-Chamber is a long, chamber, heated by hot air to a temperature above 210°, and divided into numerous smaller chambers, in which the clothes are deposited. Each division of the chamber contains a clothes-horse or maiden, one being allowed to each washer. In ten minutes, or a quarter of an hour, the clothes, unless very heavy or numerous, are quite dry. The Committee have published a table in their Report to show the rapidity with which the drying is accomplished. Some of the results are curious. We may take a single instance as an illustration of the processes we have been following. Three large dirty blankets weighed before being washed 82 lbs. 3 oz.; after leaving the wringing-machine, 12 lbs. 3 oz.; after being dried, 8 lbs. 12 oz. These blankets took twenty-five minutes to dry, at a temperature of 210°. In all other cases the results were similar; establishments, in which the temperature taken when the drying-chamber contained decidedly less moisture than they did when they were received for the "wash." To show the "satisfactory working of the drying-chamber at the Model Establishment, and also in great advantage in the economy of time, trouble, and expense..." to those of the labouring classes who resort to it," the committee give a return of the articles dried there in one week ending January 24, 1853. It is too full for us to copy; but we may state that the number of articles of all kinds, from counterpanes, jackets, and trousers, down to shifts and stockings, was 36,844, belonging to 1373 washerwomen, who occupied 3995 hours in washing, drying, and ironing them; and that the dried consumed only 285 lbs. of coke, which cost under 1s. 6d. in most of the establishments there is only one class of washers; but in some there are both first and second classes, the difference being that the first class have a somewhat larger compartment allotted to each washer, and a third or fourth washing-machine. The charge for the use of these has been described is now generally 1d. an hour, though in a few places it is only 1d. an hour. Where there are both classes, the charge is 1d. an hour first-class, and 1d. second. Soap, soda, &c., have to be bought by the washers. Unquestionably the wash-houses are, according to the size of the establishment; at Goulston Square there are 64 of them, at St. Martin's 56. The average time occupied by each washer at the Model Establishment is two hours and a half; and this is the general average given in London; in some country towns it differs considerably. In
At this time he was alike opposed to Kosuth, with whom however he afterwards allied himself. When, in consequence of the events of March 1848, the Archduke Stephen was created Palatine of Hungary, Count Louis, an old friend of the Austrian chancellor, was not less anxious than Louis de Carné to take part in the hostile struggle now become inevitable. In November 1848 he went to Pesth, to take his seat in the Diet, and was named one of a deputation sent to treat with General Windsichgratz, the Austrian general, who was approaching Pesth with an army. The deputation was not received. The Hungarian government removed to Debreczin, but Count Louis remained at Pesth, where, on the arrival of Windsichgratz on January 6, 1849, he was arrested. After being transferred to Olm, to Ometz, and to Lybach, he was at length brought back to Pesth, where he was condemned by a council of war to be hung. He endeavoured to escape the ignomy of the sentence by destroying himself with a polynard. He did not succeed, but at length the sentence was carried out, October 13, 1849. His body and that of the librarian were consigned to the flames, and his children were exiled.

\(\text{[Novelle Biographie Générale.]}\)

**BATRACHOSPERMEAE.** a tribe of plants referred by some writers to the genus *Batrachophora*; and as it is regarded by Harvey as an aberrant group of *Chlorospermeae* and *Templetonia, passing through *Ectocarpus* to *Melanospermea.* [A] or [\text{A}.] The species have a polysiphonous frond composed of a primary thread, surrounded by parallel accessory ones. The vesicles and terminal or lateral and closed.

The principal genus of this family is *Batrachospermum,* which have got this name from *Bérapex,* a frog, and *Etrico,* a seed, on account of their gelatinous fronds giving them the appearance of the ova of the Amphibia. The species are flexible, and have a gelatinous character. The surface is covered in innumerable little hairs, looking like cilia, which give them a very beautiful appearance under the microscope. They mostly inhabit pure and running waters where the force of the stream is not considerable. On removing them from the water the hairs, which are expanded whilst immersed, collapse, and they appear like masses of jelly without any traces of organisation.

Several species of this genus have been described by Dr. Hassall, as in the neighbourhood of London. *B. moniliformis* is figured in Lindley's *Vegetable Kingdom,* p. 20; and Hassall has figured some of his new species in his *British Fresh-Water Alge.*

**BAVIAN,** a small hamlet in Kaukas, situated on the left bank of the Tchagharian, on the village of Khinnis, which stands on the right bank of the river in about 36° 49' N. lat. 43° 38' E. long. The place has become celebrated in connection with the Assyrian rock sculptures discovered near it by the late M. Roset, French consul at Mosul, and since visited and described by Dr. Layard in his *Nineveh and its Remains,* and in his *Nineveh and Babylon.* The sculptures are carved in relief on one side of a narrow rocky ravine in the Missouri hills, on the right bank of the Goyel, a stream which joins the Tchagharian in the north-west just above Bavian. The sculptures are cut in the face of a limestone cliff that rises perpendicularly from the bed of the torrent. The face of the cliff has been smoothed down into several compartments or tablets, each inclosed in a frame of the living rock, and protected by an overhanging cornice from the water that trickles down the precipice. The bas-reliefs, which are of colossal size and admirable execution, are of the true Assyrian type, and represent gods, nympha, and animals. They have suffered much from the effects of the atmosphere, but still more from the excavation of tombs in the 

\(\text{[E]eadly-scraped flocks, by some people who occupied the country after the Assyrians. The faces of the tablets are inscriptions in the cuneiform character, which were copied by Dr. Layard, and have been translated by Dr. Hincks. These inscriptions recoup the exploits of Sennacherib, and are considered to be of considerable historical importance.} \)
BEAUFORT, REAR-ADMIRAL SIR FRANCIS, K.C.B., F.R.S., &c., late Hydrographer to the Admiralty, is the son of Captain John Beaufort, of the county of Meath, Ireland, and author of Map of Ireland, published with a memoir, in 1792, as well as of some theological publications. Francis Beaufort entered the navy, in June 1787, as a volunteer on board the Colossus 74, stationed in the Mediterranean. He was detailed to the Phaeton, a privateer, in June 1790, and while holding that rank saw much active service, assisting among other duties in the capture of several vessels. In May 1796 he was created lieutenant, and whilst acting as a lieutenant of the Phaeton, 36 guns, he, having under his orders a barge and two cutters, hoarded and took the San Joseph, a Spanish polacule-armed ship of 14 guns and 56 men, which lay moored under the protection of five guns of the fortress of Fuentsizola, near Malaga, supported by a French privateer. While in this service the lieutenant received a wound in his head, and several slugs in his body and left arm; but was recommissioned by obtaining, as a recognition of his skill and courage, a commander's commission. During a cessation from service afloat, he was engaged from November 1798 to June 1804 in superintending the construction of a line of telegraphs between Dublin and Galway. In June 1805 he proceeded as commander of the Woolwich 44 guns, to the East Indies, and was appointed to the Praza, of 74 guns, while a lieutenant, during the campaign of 1807, a very valuable survey. He was afterwards stationed at the Cape of Good Hope, and in the Mediterranean. In May 1806 he was appointed to the command of the Blossom, and the following year with the rank of a lieutenant on the command of the Frederickson's frigate. During 1811-1812, he was engaged in making a minute survey of the coast of Karamania in Asia Minor, but was compelled in the latter year to return home in consequence of wounds inflicted on him by a fanatic Muslimman.

In the course of these services Captain Beaufort had obtained a very high rank, as a scientific as well as a brave seaman, and equally so as a hydrographer and geographer. He was now consequently called upon by the Board of Admiralty to assist in the compilation of the works, in a series of charts, the results of his various surveys. Among other charts constructed by him were one of the Archipelago, three of the Black Sea, including the coast of Asia, and seven of Karamania, these last being accompanied with a "Memoir of a Survey of the Coast of Karamania in 1811 and 1812." In 1817 he published in 8vo, a fuller and more elaborate work on the same district: Karamania; or, a brief description of the South Coast of Asia Minor, and of the islands near thereto; &c., with maps, plans, &c. His labours and scientific merits found their appropriate reward in his elevation, in July 1832, to the post of Hydrographer to the Admiralty, to which important office he imparted new honours, in which he held for 18 years, and during which he continued to hold till he retired full of years and honours on the 30th of January 1855, having very nearly completed his 68th year of service. He was succeeded by Captain Washington, Admiral Beaufort died in Dec. 1857.

In April 1836, Captain Beaufort was appointed Commissioner for Inquiry into the Laws, &c. affecting Pilots; and in January 1845 a Commissioner for Inquiry into the Harbours, Shores, and Rivers of the United Kingdom. He was created Rear-Admiral, Oct. 1, 1846.

Admiral Beaufort, besides his memoirs on the coast of Karamania, &c., contributed papers to the Geographical and other learned societies; and the important collection of Maps of the Society for the Diffusion of Useful Knowledge was executed under his supervision. He was elected Fellow of the Royal Society in June 1814; he was also a Member of the Council of the Geographical Society, a Fellow of the Royal Astronomical Society, a Corresponding Member of the American Geographical Society, &c.

BEAZLEY, SAMUEL, architect and playwright, was the son of a surveyor in Parliament-street, Westminster, where he was born in 1786. In early life Mr. Beazley served as a volunteer, and some of his adventures in the Peninsula and France, which remained to himself, are his own character. Mr. Beazley's chief claim to remembrance as an architect arises from the fact of his having erected a larger number of theatres than any other contemporary architect in the United Kingdom, or in Europe. The Lyceum (both the present one of that name, and the one on its site destroyed by fire in 1830), the St. James's and the City of London theatres in the metropolis were built by him; also two or three in the provinces, and two in Dublin. He likewise furnished the drawings for two in Belgium, one in Brazil, and one in Russia. Mr. Beazley was a founder of the Royal Institute of British Architects (1785), and the colonnade of Drury-lane theatre were also erected by him; and we believe that he executed other works in connection with theatres. His theatres, though not remarkable for any high degree of artistic design, yet possessed the whole of the audacity a tolerably good view of the stage, while their acoustic properties are considerably above the average. Among his other more important works may be mentioned Studdy Castle. For some years before, he had been very extensively employed in constructing the architectural works of the South-eastern Railway Company. The terminus at London Bridge, the stations on the North Kent line, the New Town, Ashford, Kent, the Warden Hotel, and the Pilot House, Dover, &c., have been chiefly planned by him. His theatres are mostly well adapted to their purpose, and like them, they have little other merit.

But during his life Mr. Beazley was not merely known as an architect. He was also one of the most prolific playwrights of the day, having written, it is said, upwards of a hundred dramatic pieces. They were mostly farces, and other light occasional pieces, which were forgotten by the end of the season in which they were produced; but one or two still occasionally reach the stage, and give the audience considerable titillations; but, like his buildings, they appear to have exhibited great mechanical dexterity, and a keen perception of the immediate requirements of the subject. Mr. Beazley wrote two novels, the 'Octariana,' and the 'Ward,' the latter was published during the vogue of the 'Sonnambula' and some other operas. Though apparently so constantly employed, Mr. Beazley was well known in society as a dapper and a cheerful companion. He died suddenly at his residence Tunbridge. The Architectural Review 1851.

BEDALE. [YORKSHIRE.]

BEDWYN, GREAT. [WILTSHIRE.]

BEECHEY, ADMIRAL FREDERICK WILLIAM, was the son of John Beechey, of Hertford, and was born in London in 1766. Having entered the navy when only ten years old, he was engaged as early as 1811 in an action off Madagascar, resulting in the capture of the French frigates Renommé, Clarinde, and Nétrie. In 1818, when the Dorothen under Captain David Buchan, and the Trent under Lieut. John Franklin, were despatched in search of the northwest passage, Beechey sailed with Franklin, with the rank of lieutenant. Lieut. Beechey had already distinguished himself in the burning of the French ship, thehistory, and it was given to his charge to collect and preserve such objects as were practicable, or make drawings of such as were not. This voyage, though unsuccessful in its main object, contributed many useful results, and gave him the satisfaction of accounting them in a narrative of the voyage was published by him in 1843. For the ability displayed as an artist in the voyage he was rewarded by a parliamentary grant of 200l.

In 1816 Lieut. Beechey took part in an expedition under the command of Sir Edward Parry (then commander), which penetrated to 113° 54' W. long. within the arctic polar circle. In 1821 he was commissioned, together with his brother, H. W. Beechey, to investigate by land the coasts of North America to the east of Tripoli. Of this undertaking he published a most interesting narrative, with descriptions of the ancient Syrtis, Pentapolis, and Cyrenaica, with a valuable and detailed chart of the coast, extending from Tripoli to Derna, or from 13° to 28° E. long. After his return home he was appointed to the command of the Blossom, with the rank of commander, and directed to endeavor to penetrate the Polar Sea by the Pacific Ocean and Behring's Strait, while Franklin made the attempt overland from North America. Beechey sailed in 1836, and remained in the service till 1846; the voyage having been only half. The extreme point reached in boats was 71° 23' of N. lat., and 166° 21' of W. long. While at Barrow Point, Franklin was at Point Turnagain, thus they were only 100 miles apart. In 1837 Beechey was appointed to the command of Sir Edward Parry's second voyage, and, though neither advanced. In 1837 Beechey received the rank of Post Captain, and during the summer of this year succeeded in discovering to the south-east of Cape Prince of Wales, and near to Behring's Strait, two most convenient barbours, to which he gave the names of Port Clarence and Port Grantley. After this voyage Captain Beechey remained un-
employed for some time, as his health had suffered; but he occupied himself in preparing and publishing accounts of the various voyages. In 1857, at the year of his return, appeared 'Proceedings of the Expedition to the Northern Coast of Africa, from Tripoli, eastward, in 1821 and 1833,' the 'Voyage to the North Pole' followed; in 1851 appeared the 'Narrative of a Voyage to the South Seas the year before last.'

For his services, he was made Rear-Admiral of the Blue. He died November 26, 1858.

BEES, ST. [CORNwall].

BELDING. [Northwestern].

BELFORT. [Baroda].

BELGIAN CONGO, S. L.

BELLINGHAM. [Northwestern].

BELLOT, JOSEPH RENE, was born at Paris, in March 1828. His father, who, was in humble circumstances, removed to Rochefort when Joseph was five years old. Joseph was placed in the elementary school at that city, and so favourable a report was made by his schoolmaster at the close of his term of instruction, that the municipality at once granted him a demi-nourshe at the College of Rochefort. Here his progress was so rapid as to force the conclusion of his term ended, in his 16th year, and he proceeded to the naval school at Brest; the municipality of Rochefort continued to contribute a moiety of the expense. He was two years at the naval school, and on quitting it took rank as fifth on the list of the whole body of cadets, at the end of his first year. At the close of the second year, he received his commission as "élève de marine" on board the corvette Bréscar, bound for the Ile of Bourbon. It is worthy of remark, as characteristic of Bellot's excellent disposition, that, having been ordered to a private subscription to be assessed to his family the sum of 20 francs a month.

Bellot remained abroad some three years, returning home in November 1847. During this time, while steadily pursuing his private studies, he had, by the diligent discharge of his duties on the lower side of the ship, received the approbation of his superior officers. M. Romaine Desfossés, the commodore, to whom Bellot had acted as aide-de-camp, in his official despatch to the minister of marine, pronounced Bellot to be "the most distinguished élève on the station, . . . . . . . . and in every respect superior to his age and position." Distinguished merit in a young officer is seldom neglected by the French government. For his conduct and bravery in the expedition against Tamatave, Madagascar, in July 1846, in which he had performed the most hazardous services, he was designated as an élève of the first class, and, though under twenty, created a Chevalier of the Legion of Honour; and now on returning home with the high commendation of M. Desfossés, he was raised to the rank of Sub-Lieutenant.

The 18th of December, Bellot sailed in the corvette Triomphe to South America, where he remained for about two years. His conduct here affords a fine lesson for the young officer, whatever service he may be in, and to whatever country he may belong. His strictly professional duties, and they were very numerous, were most carefully and sedulously performed, and he obtained, as before, the warmest commendations from his superiors. But his own time was carefully husbanded and admirably employed. He not only extended his knowledge, especially in hydrography and geography, but taught himself to speak English, Spanish, and German fluently; and, withal gave up much time and thought to what he had come to regard as an important part of an officer's duty—the training of his subordinates. So far indeed did he carry this, that, both here and on the African station, his biographer informs us, "he gave on board the vessel a course of lectures on geometry and navigation for all those seamen who, being intended for masters of trading vessels, would have to pass on their return the examination in theory and practice required by the rules of the marine."

Bellot's thoughts were now turned to a new sphere of operations. The search after Sir John Franklin and his gallant comrades had directed general attention to the Polar regions. A fish is always in demand, and Bellot, his own government would not, as he had hoped, aid in the search, he asked for, and obtained permission to volunteer his services in the expedition fitting out, chiefly at the expense of Lady Franklin, under Mr. Belgrove. He was accepted, and he sailed in the schooner Royal Albert in the beginning of June 1851, holding no declared rank, but really second in command, with the understanding that he was to act as chief officer in case of Captain Kennedy's death. Of this voyage Lieutenant Belgrove was commander, and the voluminous account of the expedition published under the editorship of M. de la Roquette, along with his memoirs. The Royal Albert was ice-locked in Furry Bay for 330 days, and was compelled to return without having obtained any tidings of Sir John Franklin; but the expedition was continued from 1852 to 1854. The latter voyage, however, did not have the desired result; and not having proceeded in the direction indicated for their search, and every man was brought home alive and in good health.

Bellot had displayed in this, as on every previous service, the most intrepid spirit, the most sagacity in the choice of his object, and had secured the hearty good-will of both officers and seamen. In England he was received with an amount of enthusiasm for which he was little prepared, and his own government marked its approbation by raising him a step in rank. But he was not disposed to rest on his laurels. He again obtained permission to volunteer in a new searching expedition, and in June 1855 set out in the Phoebus, Captain Inglefield. They anchored safely in Erebus and Terror Bay, where they were lying the North Star, but its commander, Captain Palles, had been for a month away on an exploratory journey. Captain Inglefield resolved to set out in search of Captain Palles; but the latter returned shortly after Inglefield's departure. It now appeared very desirable to fitted out a vessel especially for the purpose of a searching expedition. It is said that another vessel had been a principal object of the expedition to convey to, Sir Edward Belcher, in the absence of his captain, Lieutenant Bellot volunteered to conduct this perilous undertaking. He accordingly set out with four sailors, a canoe, and a sledge. In 1856, the 28th of May, after forty-two days of ice, about three miles from the shore, off Cape Bowden, they were caught in a gale, became separated, and Bellot, with two of his companions, drifted on a broken piece of ice to- wards mid-channel. After cheering his companions as well as he was able, Bellot crossed to the opposite side of the hummock to see how the ice was drifting. As he did not return, one of the sailors went after him; but he was not to be seen, and he was never seen again. His stick lay on the ground, into which it had had no doubt been driven by the violence of the wind. His companions happily escaped.

Thus, at the age of twenty-six, was lost one of the most promising men who have adorned the French navy. The news of his sad end was received with general sorrow in both countries. In London a meeting was held, at which resolutions, expressive of admiration and regret, were moved and supported by the First Lord of the Admiralty, the President of the Royal Geographical Society, Sir John Herschel, and the French savant and scientific men; and a subscription was authorised for raising a testimonial to his memory. The testimonial took the form best calculated to do him honour. Out of the funds a handsome granite obelisk, bearing his name, was placed in a position on the English Shore, and a portion of each of his five sisters a sum of about 3000L. was appropriated. The French government provided for his two brothers.

(Lemer, Memoir of Lieutenant Joseph René Bellot, &c.)

BELOW'S-FISH. [Ctenarchus].

BELONE, a genus of Fishes belonging to the family Scorpaenidae of the Abdominal Malacostracii. It has a head and body greatly elongated, the latter covered with minute scales; both jaws very much produced, straight, narrow, and pointed, and armed with numerous small teeth; the dorsal fin placed over the anal fin. The species are remarkable for the green colour of their bones.

One species, the Belone vulgaris, is common on the British coast. It is known by various names, but more especially that of Gar-Fish. It was placed by Linnaeus in the genus Esox, and being an inhabitant of the sea, it got the name of Sea-Pike. From the fact of its leaving the deep water in spring to deposit its eggs near the shore in the months of April and May, and thus preceding the mackerel in their annual visit to shallow water for the same purpose, it has received the name of Mackerel-Guide. Its other English names, according to Yarrell, are Greenebone, Horn-Fish, Long-Node, Gorebull, and Sea-Needle. The usual length of this fish is about fifteen inches; it has five dorsal spines, each with numerous minute teeth; the eye is large. The fish is uniformly dark in depth to the anal fin, thence tapers to the tail. The dorsal and anal fins begin and end nearly on the same line. The body is covered with minute scales; the external long rays are nearly as long as those of the centre. The upper part of the head and back is a t 2
greenish blue; the sides and belly are silvery white; the pectoral, ventral, and anal fins white. This fish is taken off the coast of England during the winter season, and Dr. Johnston says it is not unfrequently called a Sword-Fish. It is taken also on the Devonshire and Cornish coasts. The fish are brought into the London markets in the spring, and eaten in considerable quantities. The flesh has the flavour of a hind, but it is not esteemed. Great numbers are said to be taken off the coast of Holland, but they are only used there as bait. Mr. Couch says of the Gar-Fish, that it “swims near the surface at all distances from land, and is seen not uncommonly springing out of its element; it has been so long in such that it will for a long time play about a floating straw, and leap over it many times in succession. When it has taken the hook it mounts to the surface, often before the fisherman has felt the bite; and then with its slender body half out of the water, struggles against the violence of the terrors to wrench the hook from its jaws. It emits a strong smell when newly taken.” In the Ionian Islands, according to Mr. Tonna, it is caught by attaching several lines with floats to a raft. In this way a large number are taken at a very short time. Specimens of this fish have been exhibited in the Aquarium of the Zoological Society, in the Gardens, Regent’s Park.

There are several other species of Bream, some of which are said to attain the length of three feet or more, and to the British are already the Whiting or Bream, its flesh generally is wholesome. (Yarrell, British Fishes: Cuvier, Rame Animal.)

**BELPER [DERBYSHIRE.]**

**BER [IBIZA],** was born at Jarrow, in Austrian Galicia, in 1795. After having graduated in the University of Cracow, in 1810 he entered the military school at Warsaw, directed at this period by the French general Pelletier; and from this school, at the end of two years, he issued as an officer of the horse artillery. In 1812 he served as aide-de-camp in the army under Davoust, and subsequently under Macdonald, with whom he was during the siege of Ham burg. Russia having violated the capitulation, he was forced to return to Poland, residing with his father, who had an estate near Kievin. When the House of Poland was restored, he made his military career, and returned to Russia. In 1819 he was created a captain, and became aide-de-camp to General Bontemps. He was next made professor in a school of artillery newly established at Warsaw. Here he introduced the Polish army the use of the Congreve rocket, and published a work upon this instrument of destruction. Soon afterwards he solicited to be removed from this school, but the Grand-Duke Constantine, who treated this demand as an act of insubordination, had recourse to taunts which condemned him to prison. He was however released, but sent to Ketzik, and placed under the surveillance of the police.

After the death of the Emperor Alexander, Ben obtained his dismissal, and went to reside at Leopoli, in Galicia. There he devoted himself entirely to science, and commenced a work on the steam-engine. When the revolution of 1830 broke out, Ben immediately took himself to Warsaw, where he was at once a major in the Polish army; and shortly afterwards was appointed to the command of a battalion of horse artillery, in which capacity, in the face of a numerous enemy, he displayed all the knowledge of a tactician with the bravery of a soldier. After the defeat of the Polish army he led the remnant towards France, and here he remained for a considerable period in exile, gaining his living by teaching mechanics and mnemonics. He afterwards undertook to raise a Polish legion for Dom Pedro in his revolution, but the attempt proved a failure. He himself repaired to London, where an attempt was made upon his life; the ball aimed at him was arrested by a piece of money in his pocket.

On the commencement of the revolution in 1848, Bem at first attempted to organise the insurgents at Vienna, and afterwards joined himself to the Hungarian party. Charged with the command of an army to oppose the Austrians on the side of Transylvania, he at first experienced some checks, but in March, 1849, he made himself master of Hermannstadt, took Cronstadt, and prolonged the revolution that had been joined by that of Russia, called to its assistance in the previous February. He also compelled the Austrian general, Fuchner, to abandon the Banat and Wallachia. The Austrians rallied in Transylvania; and after attempting in vain to excite the Wallachians and Moldavians to rise, he was attacked and defeated at Segevar by a greatly superior force under Ludener, the Russian general. He however succeeded in re-assembling his forces, and on August 10th again sustained a defeat, in which however he could not retain for want of reinforcements. At the desire of Kosuth he entered Hungary, and on August 8th took part in the battle of Temesvar, in which the Hungarians were defeated. The Austrians, who had taken refuge in the Turkish territories, embraced the Musulman faith, was favourably received by the Sultan Abdul-1-Medjid, and was raised to the dignity of a pasha, with a command in the Turkish army. In November 1849, the exiles of the Turkish army, and several other corps had been ordered to reside, in repressing the sanguinary excesses committed by the Musulman population on the Christian residents. He died at Aleppo, Dec. 10, 1850.

**BEN, NUTS,** the fruit of *Moringa pterygosperma,* from which Ben-Oil, much used in perfumery, is obtained.

**[Moringa.]**

**BENCACA, a genus of plants named by Savii, in honour of Count Bentincas, an Italian nobleman. It belongs to the order **Cucurbitaceae,** and has but one species, *B. cerifera.*

The fruit is described as covered with hairs and a glaucous bloom. It grows in the East Indies. Linandy, in the 'Vegetables of India,' states that it is quite superior to the green melon, and states that it is identical with *Cucurbita pepo.* Anisius says that in the East it is presented at every native marriage feast, and is supposed to insure prosperity to the married pair.

**BEN BOY [ORNAMENT.]**

**BENTINCK, LORD WILLIAM GEORGE FREDERICK CAVENDISH,** commonly known as Lord George Bentinck, was the third son of William Henry, fourth duke of Portland, by Henrietta, daughter and co-heiress of Major-General Bentinck, whose son was married to the late Miss Ebrington of Canning. He was born on February 27, 1802, and though only a younger son, inherited a fortune from his mother that placed him above the necessity of adopting a profession. He however entered the army, and gradually attained the rank of colonel. But his political opinions and profound peace was not calculated to open the way to any ambitious aspirations in that direction. He therefore, when his uncle Canning became secretory for foreign affairs in 1826, became his private secretary, for which he displayed an extraordinary capacity, was treated with great cordiality, had unbounded confidence reposed in him, and it was thought a brilliant political career was opening before him. In 1827, while his uncle was first lord of the treasury, he entered parliament as member for the borough of his birth, however, was defeated in the close of his life. He however did not distinguish himself in parliament at this time, except by a very sedulous attendance: he spoke very seldom, and then not well; but he voted steadily on the side of what were known as moderate Whigs. He was an Emanicipationist at heart, and was in favour of emancipation, but not a supporter of the Reform Bill. On Canning’s death in 1827, Lord George gave an independent support (this means opposing them occasionally) to Lord Goderich’s cabinet, in which his father was in the house, that is, bringing up the minister, but by the close of Lord Ebrington’s motion that defeated the Wellington cabinet. He however continued to support Lord Grey’s government till the secession of Lord Ripon, Sir James Graham, and Lord Stanley (now Earl of Derby), to the latter of whom he was strongly united by the connexion of political opinions and the similarity of pursuits; both being strongly attached to the turf. On the accession of Sir Robert Peel in December 1834, he formed one of the small party nicknamed by O’Connell as the Derby Dilly, “carrying six in a row and playing off the court.” But he now joined the ‘Liberal or House treaty,’ by which it was asserted the adhesion of the Irish members was bargained for by the Whigs, and which ultimately led to the resignation of Sir Robert Peel in 1838, and his successor. It was a common saying at the time, that he would travel by rail to Andover to hunt, and return in time to attend the sittings of the House in the evening; throwing a wrapping overcoat of some kind over his-scarlet hunting coat, and exercising indefatigably the office of ‘whipper-in,’ in which capacity he was known as “the Old Lion.” But in 1843 the free-trade measures began to alienate many
of Sir Robert Peel's supporters; and when in 1846 he wholly
repealed the Corn Laws, Lord George went into the most
violent opposition. Three months after Peel retired, Lord
George abated but little of his animosity, although he
opposed the Whig free-traders who had succeeded him. The
country party, as it was termed, had been taken by surprise,
and knew not where to look for a leader. At length they
selected Lord George, who very unwillingly accepted the
post, but having accepted it, he threw himself into the part
with his accustomed energy in whatever he undertook. He
commenced studying statistics, he spoke on every possible
occasion, he inspired his adherents with boldness, he impeded
the advancing of all constitutional measures. But though clever,
ardent, indefatigable, and too often unspeakable, free-trade
continued its march in spite of his efforts, seconded by those
of his principal ally, Mr. B. Disraeli. He had during all these
political avocations continued his attention to racing and
race-horses, declaring on one occasion that the winning of the
Derby was the "blue-ribbon" of the turf. On the
prostration of the house in August 1848, he retired to
Welbeck Abbey for relaxation; he however attended Don-
caster races four times in one week, at which a horse of his
own breeding won the St. Leger stakes, to his great gratifica-
tion. On September 31 he left the house on foot soon after
four o'clock in the afternoon, to visit Lord Manners, at
Thoresby Park; and sent his servants with a gig to meet him a
mile or two off. Lord Manners was greatly alarmed; search was
made for him; but it was not till eleven at night that he was
found quite dead, lying on a footpath in a meadow a mile from
the house. At the coroner's inquest his verdict was "suicide by
the wounds of the heart." A lengthy life of Lord George has
been written by his friend and follower, Mr. B. Disraeli,
in 1851. (Gentlemen's Magazine; Miss Martineau, Life of Lord
George, 1855.)

BENZULE. [CHEMISTRY, S. I.]

BÉRANGER, PIERRE JEAN DE, was born in Paris,
August 19, 1790, of humble parentage, and in his earliest
years was brought up by his grandfather, a tailor. He wit-
tnessed the taking of the Bastille, in 1789, and was then
removed to the care of an aunt, who kept an inn at Peronne.
Here he first learnt to read. At fourteen he was apprenticed
to a printer in Peronne. Somewhat later he attended a private
school at Senateur, near Paris, where he was returned to his father at Paris, and having attended some
theatrical representations, resolved to attempt a comedy, and
produced 'Les Heraphroditens.' At eighteen he projected
the writing of an epic, to be called 'Grovis'; this he pro-
posed proceeding for, but had not time. He afterwards
produced verses on sacred subjects, some of which have been
given in the edition of his works edited by M. Perrotin
and published in 1834. These performances did not improve his
fortunes; and, reduced to great distress, he thought of pros-
ceding to Egypt, where Bonaparte then was, and whose first
successes had excited extravagant visions of glory and pro-
spersity among the French population. The return, however,
of some members of the expedition dissipated Béran
gue's dream, and he remained in Paris. It was at this period,
when suffering from his disappointed hopes, and even actual
indigence, that he seems to have resolved to be gay if he
could not be happy, and he produced his 'Roger Bontemps,'
'Le Grenier,' 'Les Guerres,' and 'Le Vieil Habit.' They were
not immediately successful, but in 1801 he published some
poems to Lucie Bonaparte, who promised to ameliorate his
situation. Lucie was suddenly called to Rome. Béran
gue thought himself forgotten; when a letter came from Lucie,
assigning to Béranthor his income as an pension to the insti-
tute, and the employment as an editor, and in 1809 was
appointed a clerk in the secretary's department of the
Academy. His songs were now becoming popular in
every quarter. During the "hundred days" of Bonaparte,
Béranthor, with his music, and in appropriate connection.
In 1813, when he published his first collection of songs, which
were popular throughout France, he was informed that it would
occasion his dismissal from the office he held in the
Academy. He wavered not, and was retained; but in 1821,
when the second collection was published, he was at once
discharged. He wrote more and more poignant satires upon
the government; he was prosecuted, and was sentenced to
be imprisoned and to pay a fine of 10,000 francs. Con
dined more strictly in the prison of St. Cloud, and after
some time permitted some attacks on the faults and follies of
the government, and these remarkable lyrics aided not a little
in accelerating the fall of the Bourbon.

In 1830 the revolution of July would have acted favour-
ably for Béranth's fortunes if he would have given up his
beloved independence. He says, "I was treated with as one
of the great powers; 'near all my friends have become
ministers;' 'unfortunately I have no love of sycophants, and
all compulsory labour has become insupportable.' Béran
gue was convinced that France was not fitted at this time for
a republican government, and he supported the establish-
ment of a limited monarchy. In 1833 he published his fifth and
last collection of songs, containing some of his most striking
pieces. After the revolution in 1848 he was elected in April
of that year a representative of the Department of the Seine
in the Constituent Assembly, by more than 200,000 votes;
but in May he sent in his resignation. It was unanimously
refused; but a week afterwards he renewed it, and it was
accepted.

Béranth continued to write, but did not publish. He was
known to have a large collection of songs, and, he employed
himself also with a 'Biographie' of himself and his contem-
porary fellow countrymen. In 1834 an edition of 'Memoirs of
Béranth' (Mémoires, &c.) was published by his brother-
ner, and Details concerning his Life ('Quarante-Quinze
Lettres,' &c.). In October, 1837, M. Lapointe published
'Memoirs of Béranth' (Mémoires, &c.) in November
appeared 'Biographie of Béranth' (Biographie, &c.);
and in December was published 'My Biography, by
P. J. de Béranth' ('Ma Biographie,' &c.)

The songs of Béранth have deservedly attained a high
reputation, not only in France but throughout Europe. One
charm is their complete nationalitv. The delicate wit, the
subtle satire, the indifferent denunciation, the vivid and
correct pictures, the frequent comicality of situation—are all
truly and exclusively French; and so are the faults that are
sprinkled rather too frequently through them. His command
of language and of metre is such that the significant rhythms
the words always seem to drop naturally into their places;
but this result, as he states in his 'Biographie,' was attained
by him only with great labour.

The whole life of Béranth is very remarkable. He had
become a real power in the state, under the first Napoleon.
Although he felt that there was no hope for the national
freedom of his country while that despotism endurcd, he had
a sincere admiration of the emperor's genius. Consequently
there were no personal attacks in his early songs; and when
a little gentle railing upon externals was ventured—as in
'Lé Roi d'Yvetot' and 'Le Sévaste'—it was laughed at
and applauded even at court. Béranth is considered by
his countrymen as a religious poet; this is not the impec
which an Englishman would receive. But he certainly
does not show by impurity, however he may offend by levity
and want of reverence. The songs for which he was prosecuted
were not attacks on religion, but on its false assumption.
They were considered and invested with the idea of the
conqueror. Béranth has little resemblance to our own
song-writers. He has none of the deep passionate love
depicted by Burns. He never contemplates the happiness of

'Living and being loved by one;' but

'Takes, foresees, rook' Liez ho' in a fashion that jars on English feelings of delicacy. The
passion he describes is indeed rather that which has become
appropriate to the French than to the English. The
contrast to our patriotic singer, Bibdin, is also striking.
Bibdin holds out few incentives to the sailors he addressed
beyond a sense of duty, prize-money, a picture of domestic
happiness with their Nancy, and Greenwich Hospital.
Such encouragements find no place with Béranth. The
glory of France is the most prominent inducement to fight and to die. To our other lyrical poet, Moore, he has some-what more directly presented.

BERCHEMIA, a genus of plants belonging to the natural order Rhamnaceae. Two species, B. colubris and B. lineata, are used in medicine.

BERRILL, WILLIAM CARR, VISCOUNT, the natural son of the first Marquis of Waterford, was born on October 2, 1768. He entered the army early, and while serving in Nova Scotia lost the sight of an eye from the accidental shot of a brother officer in 1786. He served at Toulon, and was in the felucca Pugna, which was taken and burned by Abercromby, and in Egypt under Baird. In 1806, having attained the rank of brigadier-general, he commanded the land forces in the expedition against Buenos Ayres, and was taken prisoner with his command by the conscripted army which escaped shortly afterwards. In 1807 he commanded the force which obtained possession of Madeira. In 1808 he arrived in Portugal with the English forces, and to him was confided the organisation of the Portuguese army, including the militia. This he effected so completely, that the Portuguese troops, throughout the Peninsular war, showed themselves worthy of fighting by the side of their British allies. On May 8, 1811, he invested the fortress at Badajoz, and on the 16th invested Seïnal Alberca. At the battle of Salamanca on 22nd July, 1812, he was wounded, and in the battle of Vitoria and Bayonne, on the 10th of April, 1814, he arrived and covered the heights before the victory of Albuera. His gallantry and bravery had been created a Portuguese field-marshall, Duke of Elvas, and Marquis of Santo Campo; and he was now created a British peer by the title of Baron Beresford. In the same year (1814) he was sent on a mission to Brazil: he returned in 1816, and after a short stay in Portugal, he repatriated to Brazil again. On his return he resumed the command of the army of Portugal, at the request of the Portuguese government, but resigned it at the end of a few years, not approving of the efforts then being made to establish a constitutional government. On his return to England in 1833 he was created Viscount Beresford. From 1828 to 1830 he was master-general of the ordnance. He continued to take an active part in politics, being strongly attached to the Tory party; and in 1839, in consequence of assisting in forwarding English troops for the support of Don Miguel, he was deprived of his rank as Portuguese field-marshalm. In 1835 he married Louisa, his cousin, the daughter of the archbishop of Tavarn, and the wealthy widow of Thomas Hope the banker, but left no issue. He died at Bedgingbury Park, Kent, on January 8, 1864. At the time of his death he was governor of the Royal Military Academy at Woolwich, and governor of the island of Jersey.

The family of plants belonging to the natural order Aurantioceae. B. Konigii possesses stomachic and tonic properties, and an infusion of the leaves is used against vomiting. The green leaves are used raw in dysentery; the bark is internally and externally remittent.

BERKELEY, a genus of Dicotomaceae, named by Graville, in honour of the Rev. M. J. Berkeley, distinguished for his researches in cryptogamic botany. It belongs to the suborder Nonglueae, and is characterised by having linear frustules included within tubular frustules, numerous, filamentous, which are free at one extremity, but have the other immersed in a gelatinous tubercle. B. fragilis is found parasitic on Zostera marina, and some of the smaller alga being on the abaxial coast. B. Adriatica has been found on the coast of the Adriatic.

BERMONDSEY. [Surrey.]

BERTHOLETLA. [Materia Medica. &c. 2.]

BERRILLUS (or BENZEL), JQNS JACOB, one of the most distinguished modern chemists, was born August 20th, 1779, at Wissingenda, a village near Linkoping, in East Gothland. Beyond the fact that he received the elements of learning from his father, who was parish schoolmaster—a functionary of some consideration in Sweden—and that he was sent at the age of twelve to a school, he never made any public account of his early years. At the age of seventeen the youth entered on the study of medicine at the university of Upsal, and attended the dull lectures on chemistry delivered by Alfred Berzelius. So little care had he to render scientific instruction clear to the mind, that Berzelius had to discover and investigate facts and draw conclusions for himself, and soon became remarkable for his diligence and discernment. As an instance of the way in which he was led into chemistry, let me relate what I laughingly to relate in after life: "—Alfælius first gave me sulphate of iron to calcine in a crucible, for the preparation of colochofer: ' Any one may do work of this kind,' I replied; ' and if this be the way you are to teach me, I may as well learn it by rote.' "—"Oh no! your next preparation shall be more difficult." On the next, occasion I got cream of tartar to burn, in order to make potass, which so disgusted me, that I vowed never to ask for any further employment." But he continued to attend night classes, and after a while he was sent to Berzelius' laboratory every day, although by the rules pupils were entitled to admission but once a week, his masters offering no opposition. Ekberg was, however, vexed at times that the young man did not see the fun in his chemical experiments. "I preferred," said Berzelius, "to endeavour to instruct myself by reading, meditating, and experimenting, rather than question men without experience, who gave me replies, if not evasive, at least very little satisfactory on the subject of phenomena which they had never observed." In 1796, after two years' study, he left Upsal, and engaged himself as assistant to the physician-supintendent of the mineral springs at Medevi, a watering-place much resorted to by the Swedes. Here with his habitual diligence he worked another year, and in 1799 published a small paper embodying the results. This was the first of the long series of papers that remain to illustrate his fame. In 1804 Berzelius returned to Upsal, and took his degree of doctor of medicine. He published" Researches on the Effects of Galvanism on Organised Bodies," a work which exhibits much of his sagacious insight and painstaking. Davy, who was born in the same year with the illustrious Swede, had made known his experiments; and although Berzelius, taking up the subject, found a wonder of phenomena, materially widened his applications. His growing reputation gained for him, on his going to reside at Stockholm in 1805, the post of assistant to Sparrmann, professor of chemistry, and Davy, who had asked admission to Gooch's second voyage of discovery. The emoluments were so scanty that Berzelius had at times to practice medicine to eke out his resources. In 1806 he succeeded to the chair, and in the same year, jointly with Hisinger, he commenced the" Afhandlingar i Fysik, Kemi, och Mineralogie," to which during the twelve years of its existence, he contributed forty-seven original papers. This periodical was at once translated into German, and subsequently into French, and generally prized for its trustworthy elucidation of chemical principles. This however, but a small part of his work: in 1812, a young man took: he set to work to revise the labours of his predecessors, accepting no conclusion that did not admit of the clearest demonstration. His skill as an analyst is described as singular; and when Dalton was about to give his views he, by innumerable analyses, established the laws which regulate chemical combinations, and reduced them to a form so simple as to give them a twofold value. "When confronted with laws once well ascertained," says an eminent foreign writer, "it became possible to combine the results of the analyses—even to foresee a great number of combinations then unknown—and to carry into every operation an accuracy previously thought altogether unattainable." By his elaborate examinings and experiments with the salts and going through the whole range of elements, including the products of organised existence, Berzelius anticipated Dalton in some of his conclusions, and afterwards found a perfect agreement between his results and those of the Manchester philosopher. His knowledge of the laws of definite combinations enabled him to elucidate the nature of minerals, and to show at the same time, by the composition of the minerals, the universality of the laws. He helped indeed to bring the atomic theory to perfection, and introduce it into science. He framed moreover an electro-chemical theory, and published" Lectures on Animal Chemistry," a work filled with rare proofs of original research and clear perceptions on a branch of science then least understood. On the publication of this work Berzelius was not able to pay the expenses of two hundred dollars a year, to enable him to better prosecute his labours. In 1807 he joined with seven leading members of the profession in establishing the Medical Society of Stockholm, and all the following year he was admitted a member of Sciences of Stockholm. In 1810, being then at the age of thirty-one, he was elected President of the Academy;
The life of Bernhard Senior became a most important instrument in the analysis of inorganic substances. A translation of his treatise on the subject appeared in English in 1811, and it was the first edition in the chemical language.

The question of the origin of the chemical elements and the examination of minerals. There was scarcely a question that he did not bring to the test of experiment, and reduce to its proper place in science, as may be seen in his great work 'Lehrbuch der Chemie,' which has been translated into several editions, and as many translations. The last was published at Paris, in six volumes, octavo, in 1845-1850.

In 1832 Senior resigned the professorship which he had held for twenty-six years; but still kept on with his scientific labours. In 1836, four of his works were published by subscription; and the king of France, in a letter, expressed his appreciation of the work. It was with regret that he was deprived of the chance of carrying on his labours; and he died in London on the 22nd of July 1874. His father was a civil officer (justizrat) under the Prussian government; his mother a dervish's daughter; and there being a family of nine children to rear on but narrow means, the future astronomer received only an ordinary education. Among his earliest manifestations was a dislike of classical literature, and a love for arithmetic. His quickness in calculation led to his being aridoted at the age of fifteen as clerk in a mercantile house at Bremen. Here he showed himself diligent to fulfil the duty of his office; but lay immediately before him, who it might be, and this remained his especial characteristic. The hope of being offered the post of supercargo on a foreign voyage was then his stimuli; and to qualify himself for this responsible office he began to study navigation, and soon all his spare hours, chiefly in the night, were devoted to it. There was no longer the same clerical or commercial pursuits, or in the hope of a voyage. And now appeared a trait that marked his character through life—turning theory or knowledge to positive and practical nesets. With a rude wooden sextant made by a carpenter, and a common clock, he began to make time-observations; and having observed the oscillation of a star by the moon, he got thereunto, to his great joy, an approximate latitude of Bremen.

This was one of the successes that galden the heart of the student, reported in a letter to a friend. From this time his progress in astronomical studies was surprisingly rapid. While still a clerk in a counting-house, he had formed designs of original inquiry, such as are expected only of those who have thought for themselves. Bessel's work on Halley's comet was the result of these inquiries. The idea of a planet in the regions of Neptune has been published by Olbers, according to the theory of that philosopher, as a planet located in the region of Neptune. Bessel's work in this respect was the result of his observations, and he published it in 1845. The new planet was discovered by Olbers, and named the Bessel's planet.

Bessel was one of the first to observe the parallax of the fixed stars, and he published his results in the 'Journal of the Royal Astronomical Society,' and in the 'Verhandlungen der Königlichen Akademie der Wissenschaften zu Berlin.' His work on the parallax of the fixed stars was the result of his observations, and he published it in 1845. The new planet was discovered by Olbers, and named the Bessel's planet.

His work on the parallax of the fixed stars was the result of his observations, and he published it in 1845. The new planet was discovered by Olbers, and named the Bessel's planet.
The king of Prussia having resolved to establish an observatory at Königsberg, Bessel was appointed director in 1810, and roused himself, he supervised the long and arduous mounting of the instruments, fulfilling at the same time the associated duties of professor of astronomy and mathematics in the university. The establishment, which was finished in 1813, remains no less a monument of his skill and earning power than the man; it sufficed amid the distractions of war. Observations were published in the same year, and have been continued ever since with incalculable benefit to practical astronomers.

Settled in a congenial home, Bessel married with the utmost happiness. His wife was the daughter of Dr. Hagen, a learned man who had been her son and two daughters. And now, what he had done for the comet observations of 1607, he—also at Olbers' suggestion—undertook for Bradley's Greenwich observations, which, first published in 1814, but little regarded by the astronomers of the day. He had begun the task of digestion and reduction in 1807, and applying himself to it as he had numerous avocations admitted, brought it to a close in 1818. The results of this long-continued labour have been for many years before the world in a folio volume, entitled 'Fundamenta Astronomica.' This work, published when the author was in his thirty-fourth year, is of such a nature that even grave philosophers can scarcely speak of it in sober terms; and it is not fitting to Englishmen, being based on the twelve years' observations of Bradly. The book indeed cannot be over-praised. In the words of a scientific report—

"Besides elaborate determinations of all the principal elements of the reduction, the errors of the instruments, the height and inclination of the body, the proper motion, processes of the proper motion, it contains a catalogue of the mean places of 3292 fixed stars, observed between 1760 and 1803, with the best instruments in existence at that time, and reduced to the epoch of 1760, with a precision and accuracy of which there was no previous example. It now furnishes astronomers with the best existing means of determining all those data which can only be deduced from a comparison of observations made at considerably distant intervals of time, and which must be regarded as having been the principal improvements which have been made in astronomy since the date of its publication."

Schumacher's note...remarkable. One may almost assure that one exact and able calculator is capable of doing better service to astronomical science than two new observatories, in this case found its verification.

Bessel's reputation was established. In 1822 he was elected a foreign member of the Astronomical Society of London, and later of the Royal Society; and the scientific societies on the Continent gave it a signal to enrol him among their associates. The king of Denmark conferred on him the order of the Dannebrog; and from his own sovereign, whose life was his steady friend, he received the order of the Civil Merit of the Red Eagle, third class of the Councillor; and the Berlin Academy awarded him their prize for his paper on the precession of the equinoxes.

Bessel's labours have been so numerous that anything more than a bare enumeration of them is scarcely possible. He improved the method of finding longitudes. He determined the length of the seconds' pendulum at his own observatory, and so perfectly, as to establish an epoch in the history of pendulum experiments. He showed that in all former observations an essential cause of error had been overlooked, namely, the mass of air dragged by the pendulum in its oscillations; and that the amount of consequent disturbance would have to be calculated for every pendulum. He investigated all the causes of error in astronomical instruments, leaving nothing unaccounted for, till he surpassed all his contemporaries in his knowledge of the theory of instruments. He employed to determine the Prussian standard of length; and in connecting the geodetical surveys of Russia, Prussia, and of the west and south of Europe; and displayed in these, as in his other labours, rare ingenuity in devising new methods and avoiding causes of error. At the same time he measured an arc of the meridian of Königsberg himself, or of his observatory, over the whole subject into view, he investigated the surveys of the British government in India and elsewhere, and of the French from the Belgian frontier to the Mediterranean, shrinking from no toil that might aid in the accomplishment of his object. The result of the investigation had been calculated and allowed for by four independent geometers; but Bessel, not satisfied with this, "actually recalculated the whole of the work by his own method, producing a result agreeing with the mean of the four determinations allowed for, and established the rectitude of his method, which had been tried on for three years a series of observations on the star 61 Cygni, to determine if possible the annual parallaxes of a fixed star—a task which had been the ombroprism of science. Thanks to his marvellous skill and delicacy of perception, he found an error in the parallax of the star! This is almost inconceivably small, only 30-100ths of a second, astronomers agree in considering it as demonstrated. By observations of other fixed stars, Sirius and Procyon, he "thought himself authorised to announce the want of nuance' in parallax."

Sir Patrick Bronte, in his History of British Astronomy, says—

"And he threw out a speculation as to the cause; namely, that the stars in question are double stars, of which one is not luminous; hence we see the disturbances, but not the distinctness of them."

More trustworthy guides than Bessel could not be followed; to his example the present excellence of astronomical science in Germany is due. He was a copious writer; the more remarkable, as his writings exhibit proofs of so much profound research, as of variety of attainments. His "Tabulae Regiomontanae," which may be regarded as a supplement to the 'Fundamenta,' &c., appeared in 1830. Nearly two hundred papers, neither short nor unimportant, in the 'Astronomische Nachrichten,' bear his signature; and the 'Handbuch' of the Berlin Academy and in scientific journals, some of which are named above, he published also two volumes of 'Astronomische Untersuchungen,' and, as is said, left a third in preparation, on the causes of the precession and nutation, and honored in a way accordant with his desert. There is reason to believe that on his return he intended to investigate the problem which, in the hands of Adams and Le Verrier led to the discovery of Neptune. The preliminary reductions were made; but the failure was due to a young man of great promise, who died in 1841, and the approach of disease of a very painful nature upon the astronomer himself, stayed his inquiring spirit. His sufferings became...the expedition to the Great and to the Fangus growth in the abdomen. He died on the 7th March, 1846, at the age of sixty-two.

William Betham, author of "Genealogical Tables of the Sovereigns of the World," folio,1795, and of a "Baronetage," in 5 vols. 4to published in 1801-1805. Although young B...thought to be...superseded him as Ulster King of Arms in 1820. Mr. B...was appointed Genealogist of the order of St. Patrick in July 1815, on which occasion he was knighted. He also received the appointment of Deputy Keeper of Records at Dublin; an office...have under his control a large number of records, of which he availed himself to form a...extending to 40 large folio volumes. Sir William was like...diligent collector of old manuscripts connected with Irish history and antiquities: his collection was purchased by the state in 1831, and...a member of the Irish Academy, and soon after became its foreign secretary, which office he held till 1840, when he resigned it in consequence of the council refusing admission in the 'Tras...of him amidst the instructor, and some of his...variety of very singular and wholly untenable character. For a long series of...interested himself in the...collected, and he fancied that he had discovered traces of the...early days of his father, who...members of the...hypotheses...considered Bessel, not satisfied with this, "actually recalculated the whole of the work by his own method, producing a result agreeing with the mean of the four determinations allowed for, and established the rectitude of his method, which had been tried on for three years a series of observations on the star 61 Cygni, to determine if possible the annual parallaxes of a fixed star—a task which had been the ombroprism of science. Thanks to his marvellous skill and delicacy of perception, he found an error in the parallax of the star! This is almost inconceivably small, only 30-100ths of a second, astronomers agree in considering it as demonstrated. By observations of other fixed stars, Sirius and Procyon, he "thought himself authorised to announce the want of nuance' in parallax."

Sir Patrick Bronte, in his History of British Astronomy, says—

"And he threw out a speculation as to the cause; namely, that the stars in question are double stars, of which one is not luminous; hence we see the disturbances, but not the distinctness of them."

More trustworthy guides than Bessel could not be followed; to his example the present excellence of astronomical science in Germany is due. He was a copious writer; the more remarkable, as his writings exhibit proofs of so much profound research, as of variety of attainments. His "Tabulae Regiomontanae," which may be regarded as a supplement to the 'Fundamenta,' &c., appeared in 1830. Nearly two hundred papers, neither short nor unimportant, in the 'Astronomische Nachrichten,' bear his signature; and the 'Handbuch' of the Berlin Academy and in scientific journals, some of which are named above, he published also two volumes of 'Astronomische Untersuchungen,' and, as is said, left a third in preparation, on the causes of the precession and nutation, and honored in a way accordant with his desert. There is reason to believe that on his return he intended to investigate the problem which, in the hands of Adams and Le Verrier led to the discovery of Neptune. The preliminary reductions were made; but the failure was due to a young man of great promise, who died in 1841, and the approach of disease of a very painful nature upon the astronomer himself, stayed his inquiring spirit. His sufferings became...the expedition to the Great and to the Fangus growth in the abdomen. He died on the 7th March, 1846, at the age of sixty-two.
tion of the Celtic races with several of the most remarkable
racial events of antiquity. His first separate antiquarian publica-
tion, "Irish Antiquarian Researches, or Illustrations of Irish
History," 1826-7, contains many of his peculiar views; but
they then appeared in full force in a two principal works of
his class, the titles of which will sufficiently indicate the
character of his notions: the first of these was entitled
"The Gael and Cimbri; or an Inquiry into the Origin and
History of the Irish, Scotch, and Celts," 1827; and the
other, "The City of Cimbri and Gauls, as described by
Cato, and illustrated by登入s," 1828. In 1830, he
stopped the expansion of his opinions was not arrived at till
some eight years later, when appeared his "Eturia Celtica,
Essay Historical and Antiquities Investigated," or the
last volume of his "Celtic system," in which he identified
"the Chris-Celt, and both shown to be Phthiotic," 2 vols.
In 1832, he also contributed numerous papers on Irish
Antiquities to the "Transactions of the Irish Academy,"
which have their value unfortunately greatly lessened by
his strange want of critical discernment. Sir William was
deemed a Fellow of the Society of Antiquaries, London, in
1825, but only two or three papers by him were printed in
its "Archaeologia." 

In his own proper line of research Sir William was a far
more successful and able guide. Besides several genealogical
memoirs, and a valuable work on "Parliamentary and Feudal
Diplomatics," Sir William published in 1834 a able and learned
"Treatise on the Origin and History of the Constitution of
England," and in 1836 another, "The Churches of England, and
the State in the 17th Century," from which he was induced to
write his "Czech, and other Religious Tribes," 1837, 8vo.

For many years before his death Sir William occupied a
prominent place in the general and literary society of Dublin;
and he was looked up to as a leader in most of the religious
and charitable as well as the literary and scientific move-
ments of the time. Evidently courteous to all
who sought his advice or assistance, and always ready to
place his stores at the service of the historical or antiquarian
inquirer, his death, though at a ripe old age, was generally
regretted. He died at Dublin, October 22, 1850, aged
eighty years and six months.

BETHANY, a village 3 miles E. from Jerusalem, on the
road to Jericho, at the eastern base of the Mount of Olives,
was the scene of the raising of Lazarus from the dead. It is
located in the hill district of Annach (the Village of Immus).

Geography.

SHOPAL. [BoPAl]}

BICKERSTAFF, ISAAC, was born in Ireland probably about
1726. He was one of the pages of Lord Chesterfield, who became Lord-Lieutenant of Ireland in 1746. After-
wards he became an officer in the marines, in which service
he continued until forced to quit under circumstances of a
highly discredit able nature. He is known as the successful
author of a number of light comedies and musical pieces
produced under Garrick's management, of which some yet
remain in possession of the stage. The principal are—"Love
in a Village," 1768; the "Maid of the Mill," 1768; "Love in the
City," 1770; "The Cog" (a burlesque on Shakespeare's
"The Hypocrite," 1768; "Lionel and Clarsissa," 1769; "The
Pallock," 1769; "The Captive," 1769; "He Would if He
Could," 1769. His last piece, "The Sultan," was produced in
1757. The music to many of these pieces was composed by
Charles Dibdin. The time and manner of Bickerstaff's
death are uncertain: all that is known is that he withdrew
to the continent, and died in obscurity. (Biographia Drama-
tica: Thespian Dictionary.

BICKERSTAFF, EDWARD, was born March 19,
1756, at Kirkby Lonsdale, Westmorland. He was the fourth
son of Mr. Henry Bickerstaff, a surgeon of that town, and
the younger brother of the late Lord Lonsdale, Master of the
Rolls. He received his early education at the grammar school
of Kirkby Lonsdale, but was removed thence on receiving a
Here he remained for six years, when he was received into
the office of Mr. Blesland, a London attorney, as an articled
clerk. Having completed his term of five years, he entered
into partnership with his master, and on his death married
and commenced business as a solicitor at
Norwich in 1812.

The business soon became a flourishing one, and Mr. Bicken
staff, in a few years, had become deeply impressed with the importance of religious
truths, and he soon took a prominent part in the various
religious movements for which Norwich was becoming cele-
larized. The Norwich Church Missionary Society was founded
by him, and he was active in promoting the operations of the
Bible Society, and several other religious societies in that
city. He also wrote and published, in 1814, A Help to the
Study of the Scriptures, which in its enlarged form has
been extensively used. He also had an enormous circle of his own strong religious
feelings, aided perhaps by an acquaintance he had formed with Mr. Pratt, Mr. Budd, and some other leading clergyman
of the "evangelical" section of the church, led him to desire
honor to himself and in the ministerial office—a desire
which those who knew him best believed to be the true
spiritual end of Mr. Bickerstaff was, December 10, 1815, ordained a deacon
of the Church of England; the bishop of Norwich having
been induced to dispense with his case with the usual university
examinations, and to admit him as a member of the Church
Missionary Society were anxious to obtain the services of Mr. Bickerstaff to proceed on a special mission to inspect and re-organize the stations of the society in
Africa, and to act afterwards as their secretary. A fortnight
before the Bishop of Gloucester admitted him to full orders,
and he almost immediately departed with his wife to Africa.
He returned in the following autumn, having satisfactorily
accomplished the purposes of his visit.

He continued in the sessions discharge of the duties of his
secretaryship, and after fifteen years, organized new and
visiting old branch associations, directing the studies of the
missionaries, continually advocating the interests of the
society in the pulpit and on the platform, as well as with
his own active energy and influence, was through all parts of the kingdom, acquiring a constantly
increasing amount of influence and popularity in what is
commonly designated the religious world. At the end of
1830 he resigned his office, and also his ministerial charge
to the Clerical Mission. In 1831 he went to Watton
in Hertfordshire. At Watton, Mr. Bickerstaff spent the
remaining twenty years of his life. But his labours were
by no means bounded by his parish. He was during the
whole of that time in constant request as the advocate, by
sermons and speeches, not only of almost every other religious society connected with
the church, or in which, as in the Bible Society, and the Evang-
elical Alliance (of which he was one of the founders),
churchmen and dissenting associates, and in the promotion
during his residence at Watton a constant succession of
religious publications, which were for the most part read
in the circles to which they were chiefly addressed with
the greatest avidity. Indeed it may be said that during
most of these later years of his life Mr. Bickerstaff
was one of the most influential and generally popular clergy-
man of that section of his brethren among whom he was
classed.

During this period he took a very decided part in all those
measures which he regarded as having a direct bearing on the
religious condition of the country. He was especially earnest
in opposing the Maynooth grant, and in calling for its with-
drawal; and he was equally zealous in denouncing the spread
of French Jacobinism in Ireland and in the British Empire in
England; yet his opposition was free from all personal bit-
terness, and his influence was directed to softening the
asperities of religious strife. In his later years he mani-
fested a growing interest in the study of prophecy. The
unfulfilled prophecies were made the frequent subject of his
discourses, and he published several pamphlets and tracts
and three or four elaborate treatises in elucidation of the
prophetic writings.

His principal works besides the "Scriptures Help" already
noticed, and a large number of sermons, tract, &c., were:
"The Christian Student;' "A Treatise on the Lord's Supper;' "A Treatise on Prayer,' "Family Expositions of the Epistles
of St. John and St. Jude, ' "A Treatise on Baptism,' "The
Signs of the Times, ' "The Prophecies of the Catholic
Christ,' "The Restoration of the Jews,' "A Practical Guide
to the Prophecies,' &c. His collected works have been published
in 16 vols. 8vo. Among his literary labours ought to
be mentioned the "Hymn-book which he compiled, and the
Christian Family Magazine," which he edited, and which
extended to fifty volumes.

Mr. Bickerstaff was in 1841 attacked by paralysis, the
result of too prolonged mental exertion. He recovered
from this attack, and resuming his labours, proceeded to a meeting of the Evangelical Alliance, thrown
from his chaise under a heavily laden cart, the wheels of
which passed over him; but though dreadfully injured he
was after a time restored to health and activity, and survived

It was also Reid professor of music at Edinburgh; and in 1848 was elected professor of music at Oxford University. He died April 30, 1856, aged 75. Sir Henry had heavy domestic trials, and he was not predestined, nor made for business; so that his later years were clouded by much anxiety and suffering.

Bishop was one of the first English composers of modern times. Had he written less he would have written better; but he was too inartistic a man to keep to one style. He never retain a permanent place on the stage, and his elaborate imitative philharmonic cantatas have long been forgotten, much of his chamber and concert music—married as it so often was to words—stands exposed to the ridicule of the public ear, and will indeed most likely be still popular when many far more pretentious pieces of foreign as well as home growth shall have passed away with their novelty. Many of his songs and glees have the truest inspiration of that strain of music—flowing, vivid, graceful, and free from all affectation. (Dictionary of Musicians; Athenæum, 1855; Gentleman's Magazine, 1855.)

BISHOP'S AUCKLAND. [AUCKLAND, Bishop's.] BITTLE, in Turkish Armenia, situated at the southern extremity of a long rocky ravine which separates the Kurk Mountains from the Nirmrud-Dagh in a deep valley traversed by the Bittel River, one of the head waters of the Fugia, a distance of about 120 miles S.E. from Erzrum, and E. of Bajaz, S.W. from Bitlis. Three ravines each traversed by a stream open into the valley, one already mentioned from the north-west, another from the west, and a third from the east; and at their junction is a great valley the termination of which is 5156 feet above the sea. In the centre of the town rises an abrupt rock 50 or 60 feet high, on the summit of which are the ruins of a castle, the residence of the former Begg of Bittle. The only access to the castle is by a narrow passage, the exit from which is defended by gates. The town wall which runs round the edge of the rock, and is 30 feet high above its level platform, is solidly built and loopholed, but within this inclosure there is nothing but a heap of ruins. At the eastern base of the castle rock are the bazaars, which are large, dark, ill-built, and dirty, but well frequented, and generally much crowded, as Bittle is one of the chief marts for the imports and exports of Armenia and Kurdistan. The bazaars are lighted only by perforations in the roofs, which is termed over and used as a highway for foot passengers. Near the bazaars and on the banks of the river are the slaughter-houses, haunted by mangy dogs, and reeking with offensive effluvia. The streets run along the streams and up the ravines, giving an irregular and straggling appearance to the town. The houses are for the most part built of wood, with one or two rooms deep, and are interspersed with numerous orchards and gardens, which smile in singular contrast with the bare limestone mountains that rise on every side to the height of about 2000 feet above the valley. The streams are crossed by footbridges, and it is impossible to afford a ready passage from one part of the town to another.

The houses are all built of stone and flat roofed. The best of them stand high up the declivities, and are ornamented with large arched windows, trellis-work, and porticoes. The stone used in building is a soft volcanic rock which abounds in the neighbourhood, especially in the north-west ravine; it is cut into square blocks which are cemented with mud; only a few of the houses are pointed with lime cement. There are three principal marts of commerce: a market of three mosques with minarets, twelve tukyevs, or convents of howling Dervishes, and four Armenian churches. The population of the town consists of about 2000 Mohammedan, 70 Armenian, and 40 Jacobite families. The principal building consisted of the fortified residence erected by the Beg of Bittle 1836, on the level summit of a mountain spur that runs half way across the mouth of the eastern ravine, and is 5475 feet above the sea. It is a rude but extensive structure, consisting of a quadrangle of two stories high, built round a court which is roofed with gables. At the four corners are four covered stables and store-houses; the upper rooms are entered from an open gallery overlooking the court, and are used as sitting and receiving rooms, harem, &c. The windows are all set in the roofs, or open on one side at the base of the building, and command extensive views. From this rising cascade, as it were, to the west and the eastern ravine, Sheriff Beg held Bittle and its territory (containing 80 villages, and forming about one-third of the pashalic of Muhub) in defiance of the Sultan.
for several years. The position of this fortress as given in the "Royal Geological Journal," vol. x., is 38° 23' 54" N. lat., 42° 46' E. long.; on the map in Dr. Layard's "Nineveh and Babylon," the town is placed 36° 20' farther east.

In point of trade Bitlis is an important place. The exports are chiefly galls, honey, wax, wool, and gum tragacanth from the mountains of Kurdistan and Armenia, carpets and cotton stuffs woven in the town and neighbourhood, and dyed here in the same manner as the rich ones of Damascus, for they are made from mountain herbs, and from indigo, yellow berries, and other materials which are imported. The raw cotton used in their manufactures is brought from the districts of Kharab and Shihok (which shallowly is called Shiah), (which it is said is furnished from Khar, in Perimia. It is spun by hand; and several hundred thousand short heavy calico pieces are manufactured throughout the country, of which Bitlis is the centre, and sent here to be dyed. The favourite colours among the Kurds are a dull red, and a bright yellow mingled or striped with black. The carpets are of a rich soft texture, with patterns displaying considerable elegance and taste; they are much esteemed in Turkey. Manchester goods, including unbleached calicoes, shawls, and prints; gay-coloured silks and satins, woolen clothes and coarse cuttersy are comprised in the list of British goods sold in the bazaars. The manufactures of Damascus, Aleppo, and Diyar-Bekr are more extensively used.

Bitlis is said to be an ancient place. Until lately it was governed by Kurish Begs, who were but little under the control of the Porte. Sherif Beg, the last of these lawless chiefs, was exiled to Constantiopolis in 1843, after the subjugation of Bitlis by the Persians, and the town was recovered under the Pashas of Mussul.

BIVALVE, a name applied to those forms of Shell-Fish which have two shells, or valves, in contradistinction to those which have one shell, and which are called Univalves. [Mollusca.] Before entering into a study of their forms, which are well known as it is at the present day, the Barnacles and Sea Acorns, which have several external valves, or shells, were referred to the Mollusca, under the name of Multivalves.

BLACK JACK, the name given by miners to the Sulphur of France.

BLADDER. DISEASES OF. [Surgery, s. 2.]

BLAINVILLE, HENRY MARIE DUCROTAY DE, a distinguished zoologist, was born at Arques near Dieppe, September 12, 1776, of a noble and ancient family. He went first to the military school at Beaumont-Auge, being destined for the army; but left it suddenly in 1796, and, as is said, shipped on board a channel cruiser, and took part in seedy engagements with English vessels. Afterwards he entered the artillery, and was sent to the school of philosophy, in which he was elected assistant in 1798, but obtained exemption through a partial stiffness of the right arm caused by an accident. He remained at Paris without any definite plan of life, occupying himself in a desultory manner by attending lectures on the natural sciences, and by drawing zoological figures. In 1800 he became very expert. He had reached the age of twenty-seven, when, having heard one of Cuvier’s eloquent lectures at the Collège de France, he resolved on devoting himself to the science of comparative anatomy, and at once entered as student in the School of Medicine. Here he took his degree of Doctor of Medicine in 1806, after three years of study; and chose as the subject of his inaugural dissertation, the influence of the eighth pair of nerves in respiration, as demonstrating the function of the diaphragm. The science of anatomy now became De Blainville’s sole pursuit. His remarkable skill as a draughtsman led to his merits being recognised by Cuvier, who employed him as practical anatomist and artist at a salary of 3000 francs a year; and the great zoologist was so impressed by his assistant’s activity, that he intrusted him to the delivery of a part of his course of lectures on zoology at the college. It was De Blainville’s ambition to become professor, and in 1812 he competed with other candidates for the chair of zoology and physiology at the College de France. Having obtained the honourable post, he defended his well-known thesis on "The Natural Affinities of the Ornithorhynchus Paradoxus." A flattering political position, obtained through his influential father-in-law, was offered to De Blainville; but he resisted the allurements of public life for his favourite science. He came to England in 1816, and during a short stay, made diligent use of his opportunities for adding to his zoological knowledge, and carried away drawings of the rare Molusca in the British Museum, and of anatomical specimens in the museum of the Royal College of Surgeons. Some of his papers, published in the "Bulletin de la Société Philoménique," bear testimony to the good use he made of his sojourn in this country. In 1825 De Blainville was elected a member of the Academy of Sciences at Paris. On the retirement of Lamarck in 1830, he was appointed to the chair of the natural history of invertebrated animals. After De Blainville’s death (20th of March) in 1832, his widow was succeeded in the chair, and acknowledged head of one of the most important branches of science. In the same year he was elected a foreign member of the Royal Society, and subsequently of the Geological Society of London, where he also a member of other scientific societies on the continent.

De Blainville availed himself of his new position to communicate what has since been recognised as his great work: "Ostéographie, ou Description Iconographique comparée du Système et du Système des Cinq Classes d’Animaux Vertébrés recouverts et fossiles," etc. Twenty-three parts of this magnificent work had been published, and the author had corrected the twenty-fourth part ("Coniuceria"), when on the arrival of Rossen a railway train in which he had taken a place, he was struck by a whirling current of air. This was the 1st of May 1850. On the previous day he had delivered his usual lecture: "exhibiting," says M. Prévost, "a freshness of ideas, and facility of expression, which bore the marks of clear thought and apprehension. Some threatening symptoms had been experienced by him, but, with a force of character peculiar to him, he had sought to conceal them from all, even from himself." All attempts at remissation proved unavailing, and he died a few minutes after his return from the audience.

The fact that De Blainville’s writings number nearly 200 in the whole, will best give a notion of his activity and devotion to science; they comprise researches in all branches of zoology. His "Ostéographie" and "Manuel de Malacologie," two large and comprehensive works, are the epitome of a life. The former includes extinct as well as living animals, and is of rare importance to paleontologists.

De Blainville had a public funeral in Père-la-Chaise. Prévost, Chevreul, and Milne-Edwards each pronounced a discourse over his grave. A passage from the former presents a concise view of what he accomplished. "It was the great object of his life," says M. Prévost, "to establish in all his works, especially in his "Ostéographie," the doctrine that each sub-group was the link of one great chain, ascending from the most simple of organisms to that which occupies the highest place; in other words, from the sponge to man. But while he endeavored to refer all groups and every variety of animal form to one and only one sub-group, he never embraced the plausible hypothesis that each higher grade had been improved in the course of ages out of a lower one by transmutation; on the contrary, he saw in the whole animal creation one single progressive evolution, and maintained that the changes being neither due to chance nor to the influence of external circumstances, but being all the result of one and the same original conception." (Proceedings of the Royal Society: Ann. des Sc.; Agassiz, Buff.; Billsman, Journal; Geo. Soc. Journal; L’Institut de France.)
large showy red flowers. The calyx is girded from four to six broad scales; the corolla with six petals; the fruit a capsule, divided from three to five nerves. B. quinquenervis, Anulet, B. tripinnatis, Linnaeus, is a native of Brazil, Guayana, and Trinidad. It produces a large yellow berry, which is eaten in the countries where it grows. B. purpureascens is a native of Guyana, and is one of the most valuable medicinal plants of the genus, yielding shrub root, rooting itself in other trees. It yields a colouring matter, employed for dyeing red.

BLANCHARD, LAMAN, was born at Great Yarmouth, Norfolk, May 16, 1805. His father having removed to London, he was settled at St. Olave, Hart Street, Southwark.

He commenced the business of life as a printer in the office. From boyhood he had exhibited a great fondness for poetry, and considerable aptitude in verse making; and his first literary achievement was a series of minstrelsy's, entitled 'The Lyric Offering,' published in 1826. Before this, however, in 1827, he had received the appointment of secretary to the Zoological Society. This office he held till 1831, when he resigned it to become acting editor of the 'New Monthly Magazine.' From this time till his death, his talents were wholly devoted to writing for the periodical press, to which he was one of the most varied and prolific contributors. His contributions consisted of poems, essays, sketches, and brief pointed paragraphs.—It is a fact well known to all who have read his journal with which he was at the time connected: and all of them displayed a lively and genial fancy and a ready wit. Mr. Blanchard edited the 'True Sun' newspaper during the wars of 1812. Constitution was his most important work, besides the 'Count Journal,' and the 'Cousier.' For some time previous to his death he had assisted in conducting the 'Examiner.' His death occurred under very painful circumstances. His wife, to whom he was much attached, became very ill about a year before his decease, and her illness ended in insanity. She rallied for awhile, but relapsed and died, under the prolonged anxiety attending her long illness and its fatal termination, his own health and spirits gave way. Guyana and Martinique were his last resorts of residence, but he was occupied, as before, with his studies. This was the fate of one of the most singular characters of the times, who, while he lived, was never known to change his habits. He was put an end to his life, February 16, 1845. His death excited much sympathy, especially among his literary brethren, by whom he was greatly esteemed. His Essays and Sketches have been collected and published, with a Memoir by Sir E. Bulwer Lytton.

BLEASSINGTON, WickeLOW.

BLEASSINGTON, MARGUERITE, Countess OF, was born at Knockbr, near Crammel, Tipperary county, Ireland, on the 21st of September, 1799, and was the third daughter of Mr. Edmund Power, of Cragg, county Tipperary, Ireland. She was married, in 1827, to a captain farmer, but the marriage was a unhappy one, and Mrs. farmer after a time. He was killed by a fall, and was put an end to his life, February 16, 1845. His death excited much sympathy, especially among his literary brethren, by whom he was greatly esteemed. His Essays and Sketches have been collected and published, with a Memoir by Sir E. Bulwer Lytton.

Bulwer Lytton.

BLESSINGTON, MARGUERITE, Countess OF, was born at Knockbr, near Crammel, Tipperary county, Ireland, on the 21st of September, 1799, and was the third daughter of Mr. Edmund Power, of Cragg, county Tipperary, Ireland. She was married, in 1827, to a captain farmer, but the marriage was a unhappy one, and Mrs. farmer after a time. He was killed by a fall, and was put an end to his life, February 16, 1845. His death excited much sympathy, especially among his literary brethren, by whom he was greatly esteemed. His Essays and Sketches have been collected and published, with a Memoir by Sir E. Bulwer Lytton.

BLESSINGTON, MARGUERITE, Countess OF, was born at Knockbr, near Crammel, Tipperary county, Ireland, on the 21st of September, 1799, and was the third daughter of Mr. Edmund Power, of Cragg, county Tipperary, Ireland. She was married, in 1827, to a captain farmer, but the marriage was a unhappy one, and Mrs. farmer after a time. He was killed by a fall, and was put an end to his life, February 16, 1845. His death excited much sympathy, especially among his literary brethren, by whom he was greatly esteemed. His Essays and Sketches have been collected and published, with a Memoir by Sir E. Bulwer Lytton.
part he held his important post, was much canvassed. But
before his watchful supervision of the general interests of
the Church, Bishop Blomfield was a careful overseer of the
duty of his diocese, and prompt to support any proposition
which appeared likely to improve the condition of the
looming classes in the metropolis. Nor in the briefest
notes of Bishop Blomfield ought the amazing success of his
efforts for increasing the number of churches to pass
unnoticed. While Bishop of Chester he zealously set
about building churches in the county, and one of his
most recent public acts was to make an earnest appeal,
secured by a large subscription, to the affluent and liberal
endowments by a vigorous effort to raise funds sufficient, if
possible, to construct as many additional churches as the
Census Report of the Registrar-General shows are still needed
to meet the wants of the vast and rapidly increasing popula-
tion of the metropolis.

The theological writings of Bishop Blomfield consisted of
"The Church Universal of the Apostles," and of numerous
Sermons and Charges.

Bishop Blomfield in 1856 resigned his bishopric, and was
successed by Dr. Tait. He died August 5, 1857, at Fulham,
noted for his liberal views in Church questions.

BLOODSTONE, also called Heliotrope, is a deep green-
stone—a jasper variety of quartz. It has obtained its name
from being spotted with red so as to resemble drops of blood.
In addition to silk, it contains oxides of iron and clay, which
arise from the oxidation of the silicate of iron. It is also
formed in the royal collection at Paris there is a bust of
Christ in this stone, so managed that the red spots repre-
sent drops of blood, (Dana, Mineralogy.)

BLOOD-VESSELS. The blood from which the tissues of
the body obtain the material of their nourishment is conveyed
from one part of the body to another by means of branch-
ated vessels which are named Blood-Vessels. It is carried along
these vessels by the impulse given by the action of the Heart.

[Space]

The vessels which carry the blood from the heart are called
Arteries, and those which carry the blood to the heart are named
Veins. (Voss.) Whilst a very generally diffused net-work of Blood-Vessels exist, connect-
ing the arteries and veins, which are called Capillaries.

[Space]

The Blood-Vessels, whatever may be their ultimate desti-
nation, seem to originate in the same manner. Observations
on this subject have been made by Schwann and Köllicher
in Germany, and by Professor Paget in this country. The obser-
vations of General Duhum were made on the circulation in
the vessels in the germinial membrane of the egg, and on the
capillary blood-vessels of the tail of the larva of a frog. Mr.
Paget's observations were made on the tissues of the foot-sheep.
According to these observations, it appears that the vessels
originate from nucleated cells, similar to those at first
constitute the different parts of the embryo. The cell-wall
external envelope of these cells shots out into slender
pointed processes, such as is seen in the forms of stellate
vegetable tissue. The projections from neighbouring cells
encounter each other, and becoming organically united, the
interwoven walls between the two projections are absorbed,
and thus a continuous tube is produced. In cases where new
vessels are produced in the neighbourhood of old ones, the
stages of the process are repeated, and a new vessel is born in
the old capillary vessels, which unite with the new, and
thus the circulation is re-established. The projections
which first united are solid and very slender, but event-
ually the intervening substance disappears and the vessels
attain a uniform caliber. In growing parts where the web of
vessels is kept up, new ones are constantly being added by
the development of stellate cells in the interstices of the
previous web. Whilst the capillaries early attain the develop-
manship of the arteries and veins, the smaller capil-
laries or veins on either side of the capillary vessels go on
increasing in size till they acquire the special membranes or
walls which distinguish these parts of the circulating system.

This distribution seems however only applicable to the smaller
vessels, and those vessels supplying the more delicate organs
are formed in a different manner, and it is there remarkable to
show that the larger Blood-Vessels may take their
shape in the same manner as the heart, in which organ there
is a sort of englomation of cells, the interior ones of which
become soft, and at last disappear, while the outside ones
become firmer and constitute the outer walls. On this
subject further observations are wanting.

(Sharpey, Quain's Elements of Anatomy; Schwann, Micro-
scopical Researches into the Structure and Growth of Animals and Plants, translated by H. Smith;
Kölliker, Handbuch der Gewebekunde der Menschen: Paget, Supplement to Müller's Physiology, by Bailey and
Kirkc.)

BOERHAEVA, a genus of plants belonging to the natural
order Orlicaeae. The species were formerly comprehended
under the genus Orlicus. One of the species B. nivea, for-
merly Orlicus niveus, is the Rhesus of Assam, and yields fibres
of remarkable fineness and tenacity. It appears from the
reinvestigations which these additional observations have
made that the celebrated grass-cloth of China is identical with the Assam
plant. Several specimens of these fibres manufactured into
light articles of dress were exhibited in the Indian collec-
tion at the Great Exhibition of 1851. The B. niveus is a
herbaceous plant, with broad ovate leaves, which are
downy and white beneath, hence its specific name. It
bears no sting.

BOERHAAVIA, a genus of plants named after the cele-
britate Boerhaave, father of the natural order Nymphaeaceae.

The species of Boerhaavia have generally emetic and pur-
gative properties, and have been employed medicinally both
by the natives of Peru and the East Indies, where the species
are now cultivated. B. tuberosa is stated by Lindley to be the Yerba
de la Purgacion of Peru, and that it is a useful vegetable.

The root of B. documbens is called Hog-Meat in
Jamaicas, and on account of its emetic properties it is some-
times called ipecacuanha in Gyanas. Sir Robert Schom-
berg has stated that it is aromatic, and is useful in dysentery. B.
documbens and B. hirsuta are also said to possess medicinal
properties. (Lindley, Vegetable Kingdom.)

BOG-IRON-ORE, a loose earthy ore of iron, consisting of
Poraide of iron and water. It is of a brownish-black
colour, and occurs in loose boggy masses.

BOOMARUS, a genus of fishes, to which the Vaagmeer,
or Deal-Fish, is referred by Schneider under the specific title
of B. Islandicus. (Trachypterus, S. 2.)

BOLODA, a genus of plants belonging to the natural order Monimiaceae. B. frangula is the Holu of Chili. It
produces an aromatic succulent fruit, which is eaten by the
natives. The wood is very fragrant, and makes a charcoal
which is preferred by the smiths of Chili to that from any
other wood. The leaves are also very fragrant. The bark is
employed in tanning.

BOISIOANDE, JEAN-FRANCOIS, was born in Paris,
August 19, 1774. Towards the end of the year 1799
Boisianne entered into the public service under the ministry
of the Interior, and was appointed Professor in the Ecole
Normal in 1795, but was restored in 1801 by Lucien Bonapar-
tre, who was then minister of the interior, and who made him
secretary-general of the professor of the Experimental
of the Haile-Marine.

Boisianne's works were published in 1802. From then Boisianne
became also a member of the Boisianne Academy and
attended also; and thenceforward devoted himself to literature,
which had indeed previously occupied nearly all his leisure
hours. He had by the year 1802 contributed numerous
articles to the periodicals of the day. In 1809 he was
appointed professor of the Greek language and literature in
the Académie de Paris, but assumed only the title of
assistant-professor, resigning the title of professor to Larcher,
who retained it till his death in 1812. Boisianne then
continued the career, and also applied his place in the Académie des
Sciences in 1809. In 1825 he was made Professor of Greek
in the College de France. Other situations of honour and emol-
ment were afterwards offered to him, but he declined to
accept any of them.

M. Boisianne occupied a considerable portion of his time
in the critical examination of Greek writers previously
meditated, and published a very large number of works and
fragments of works by Philostratus, Ptolemy, Tiberius the
Aethiopician, Herodianus, Eunapius, Aristaeus, and
several others.

In the period from 1823 to 1835 Boisianne published in
24 vols. 32mo, a 'Syloge Poetarum Graecorum,' and in con-
sequence the dictionary in 1835, in a separate copy on Mount
paper and with many corrections. By this time he had
number of the lost Fables of Babrius. Boisianne published
'Babriu Fabliae Iambicae,' Svo, Paris, 1844. (Babrius.)

Boisianne contributed to the edition of 'Athenaeus' by
Ornithology of America, or the ornithology of the United States and Europe. The Prince was always the zealous friend and patron of the votaries of science, and for many years he was the chief promoter of the annual congresses of the scientific men of Italy. He died July 30, 1857, in Paris.

Prince Charles of Napoléon married Brussels, June 30th, 1892, Zenaïde-Charlotte, daughter of his uncle Joseph Bonaparte, by whom he had ten children, of whom three sons and five daughters are living.

BONE-BEDS. Accumulations of the bones of extinct animals, more especially of fish and Saurian reptiles, are not uncommon in various strata, and have had this name given them by geologists. They generally occur at the termination of one formation and the commencement of another. These Bone-Beds are local, and are not in any case very extensive. The thickest and most widely-distributed is that of the Lias, which seems to mark the commencement of the New Red-Sandstone epoch. The most remarkable Bone-Beds are the following:

Bone-Bed at the base of the Lower Greensand at its junction with the Wealden; at the base of the Inferior Oolite, at its junction with the Lias; at the base of the Lias, at its junction with the Red-Marl; at the base of the Belle Tout Limestone, at its junction with the Old Red-Sandstone; at the base of the Old Red-Sandstone, at its junction with the Ludlow Rock of the Shropshire System. (Brodie, On the Basement-Beds of the Inferior Oolite: Pp. 89.)

BONGARDIA, a genus of plants belonging to the natural order Barleridae, or Barleraceae. (Barleridae.)

BONHILL, a town in the parish of Bonhill and district of Lanark or Lennox, Dumfriesshire, Scotland. The parish is divided in its length into almost equal parts by the south.
of Leech Loomond, and the river formed by it, the Leven, from which the district derives its name, and which falls into the Clyde at Dumbarton. The population of the town of Dumbarton hill in 1831, was 6,000.

The town is situated on both banks of the Leven, about five miles above Dumbarton. A mile nearer this town, and on the bank of the stream, is the thriving village of Alexandria, with a population of 3,781.

It is remarkable for its elegant scenery, and for the great extent of its walks and bleached pastures on the banks of the Leven, the water of which, from its softness and purity, is particularly fitted for the processes of printing and bleaching. Coals, lime, and other articles required in manufactures are brought up the river in boat, and the extensive works on the river are generally the property of mercantile houses in Glasgow. The Leven is celebrated for its fine salmon and trout.

Beside the parish church of Benhill there is a chapel-of-ease at Alexandria. At both places are chapels for Free Church and United Presbyterian Dissenters. There are also two chapels in Alexandria for Independents.

BONITO, the name of fishes belonging to the family Scomberidae. The best of them is the Bonito, or Tunny, found in the Atlantic Ocean, and in the Mediterranean Sea. It is perfectly adapted to its element. The extensive works on the river are generally the property of mercantile houses in Glasgow. The Leven is celebrated for its fine salmon and trout.

**It will be seen that many of the orders are repeated in its analysis under different divisions; and this arises from the fact that this analysis is artificial, and only expresses the partial characters of each order. Besides this, in the strongest orders, exceptions to some very general points of structure frequently occur. Thus we have apothecia and irregular-flowered plants in the polypetalea regular-flowered order *Bordeauxia.* With a little practice such an analysis as the following will enable any one acquainted with the structure of plants to refer any particular plant to its right order, and turning to the order in the alphabetical part of this work will find a detailed account of its structure and properties.**

**NOTABURS. [Britten.]**

**BOTTLE-GOURD. [LAONARIA, S. J.]**

**BOULDERs.** Of the materials of which superficial deposits of the debris of ancient rocks are composed, some are of large size, and have been called Boulders or Erratic Blocks. The portions of smaller size are called Gravel. Boulders are generally found not far from the rocks from which they have been broken, whilst gravel is carried to a great distance. Instances, however, are not wanting in which boulders have been transported an immense distance. They have been transported from Norway and Sweden to the plains of Germany, and from the mountains of Scotland to the centre and south of England. So large have been some of these boulders, and the obstacles such as interesting hills, valleys, and seas so great, that the mode of their transportation can be accounted for in no other way than by supposing that they have been floated across them massed ice, which as they have melted have dropped in the places where they are now found when those places were at the bottom of a sea. The largest boulders seem to have drifted in all cases from northern and southern points towards the warmer districts in the temperate and tropical parts of the earth.

**BOURMONT, LOUIS AUGUSTE VICTOR DE CHAISNE, MARSHAL COUNT DE,** was born at Paris, or, according to other accounts, at the castle of Bonmont, in Anjou, in the year 1773. Having entered the army in 1796, at the age of fourteen, he served as a lieutenant in the Royal French Guards until 1799, when he emigrated, and joined the army of the Prince de Condé. His sanguine disposition and earnest character recommended him so strongly to the emigrant leaders that he was immediately employed in fomenting the insurrection of the western provinces. In October 1798, he was despatched by the Prince to the headquarters of the Viscount de Sépeaux, under whose orders he commanded one of the corps of the Vendean troops, and was promoted to the rank of major-general. At this time he was only in his 21st year.

In December 1793 he was sent to England to endeavour to prevail on the British government to assist the Bourbon cause, but his mission proved abortive. He had the satisfaction, however, of seeing the Count d’Artois, afterwards Charles X, who received him in the most cordial manner, knighted him, and authorised him to confer the same honour on other loyal gentlemen adhering to the monarchical interests, and more particularly on the Viscount de Bourmont. He paid a second visit to England in 1796, exhibiting the greatest zeal in animating the French emigrants against the republic, and in collecting all the elements of civil war. Soon after he returned to France to share the perils of a new insurrection by the Vendean, and, when in the place of the Emigration in 1799, on the 16th of October of the same year he forced his way into Le-Mans, the chief place in the department of Sarthe, committing, it is asserted, great cruelties, pillaging the inhabitants of nearly a million of francs, burning the post-office, the public records, and the library in the Hôtel-de-Ville.

About the period of the 16th Brumaire, when M. de Chaumont and other insurgent leaders found it necessary to submit to the central government, the Marshal Bonmont, who had followed their example. He strove to induce Georges Ca-ndrel to do the same; but that inflexible chief, far from complying, evinced his disgust at the proposal in 1801, by ordering Bourmont’s brother-in-law to be shot. The active mind of the young soldier disposed him to a life of ease; he therefore offered his services to Bonaparte, and appears to have exhibited more eagerness than discretion in so doing. The ever-vigilant Fouché suspected his zeal; he caused the Count to be strictly watched, and, having discovered what he considered as intended, he caused him to be forcibly committed to him a prisoner to the Temple, Paris, in 1803. From this prison he was transferred to the citadel of Dijon, and thence to that of Beauchamp. Having escaped from this last place of confinement, he took refuge in the north of France, and spent some years. The French army having masters of that country in 1810, Bonmont made interest with the victorious general, was included in the capitulation, and returned to France with the army. He now submitted fully to the imperial government of Napoleon, and was offered the brevet of colonel, which he accepted. It must be observed, however, that in the vindication of his career, published in 1840 by his son, it is stated that when the Count made his submission he was at Nantes in France, and that he was allowed his liberty on condition of taking service in the army of Napoleon. His son goes so far as to assert that, in 1800, the First Consul offered him the post of lieutenant-general, which he declined.

From 1810 to 1814, Bonmont continued faithful to his new master; distinguished himself in several battles, especially at that of Nogent; and received no less than ten wounds, four of which were sabre cuts on the head. For this conduct he was rewarded with the rank of brigadier-general in 1813. He was created a lieutenant-general the following year. When the fall of Napoleon tested the character of so many generals and marshals, Bonmont only followed the example of an almost universal defection. He did not betray his chief, Louis XVIII. He did not use his sword on the very eve of his departure from the Tuileries. After the flight of the King, he did not refuse to take service a second time under the powerful man, a single word from whom would have consigned his family to ruin. But he could not brook the despotism manifested in the Acte Additonal, and tendered his resignation to the Emperor in
consequence of it. Receiving no answer, he left the French army on the 15th June, 1816, after fully communicating his design to his successor, General Hulat, to whom he explained every requisite detail of the service. Marshal Gerard, under whom he commanded a division during the campaign, and General Hulat, have, since then, exonerated Count de Bonnefont from all imputations of treachery; whilst Napoleon, in his account of the battle of Waterloo, does not even accuse him.

After his second restoration, Louis XVIII. gave Count de Bonnefont the command of a division, in the infantry of his Guards; and in this rank he served in the campaign of 1817. At that time he was sent for and on the return of the Duke to France, he appointed Bonnefont to the command of the army of occupation. In 1819 the portfolio of the ministry of war was offered to him by Prince Poldnaige; but for some decline in the offer several times, recommended other generals in preference to himself, and was only persuaded to take office by the earnest request of the King. In 1830 the great expedition to Algiers was resolved upon, and the command of an army of 37,000 troops was conferred upon Bonnefont. We have not space to follow his Algerian career. But it must be noted as somewhat remarkable, that the man, who, in a few weeks, obtained for France this large and valuable colony,—the principal conquest she has retained during the present century,—should have been the object of so little public estimation. The reverse of his career added further bitterness to that dislike, and after Bonnefont had been superseded in his command on the 2nd of September, by General Ciaouca, a charge was brought against the deposee leader, related to the manner in which the treasures found in one of the captured towns, one of his sons, had fallen in the campaign, and the custom-house officer at Marsaillle, after the landing of Bonnefont, carried his zeal to such an excess, as to examine the corpse in search for the hidden gold; and the Count has an outrage patiently, but the Countes de Bonnefont received so great a shock, that she never rallied afterwards.

From the year 1830 Marshal de Bonnefont lived in exile; residing at various times in England, Holland, Germany, and other parts of Europe, at length returning to France by Louis Philippe, and in 1840 he took up his abode with his family at the castle of Bourmont. Here he continued to reside in the greatest retirement until the day of his death, which occurred on the 27th of October 1846, at the age of 73. In France Bourmont is, of all the republican and imperial generals upon whom the charge of treason has been affixed, the most unpopular. Neither Moreau nor Pichegru, neither Bernadotte nor Marmon, has been so fully tried and condemned by the public opinion of the country, as Bonnefont. This is only his second in obloquy. After a careful examination of their real conduct, and due allowance being made for the circumstances of the time, it would not require an unusual stretch of charity to remove much of the opprobrium which now attaches to many of those names. But the time to do it effectually is not yet come; and public opinion must be respected even where most it appears to err.

(Description des Contemporains; Alison, History of Europe; Sarrut et Saint Edme, Notices; Fuller, Dictionary Historique.)

BOURNE, HUGH, the founder of the Primitive Methodist Connexion, was born April 3rd, 1772, in the neighbourhood of Stoke-upon-Trent, in Staffordshire. He was brought up in the Wesleyan Methodist communion, and became an active and zealous preacher of that body. His zeal appears to have carried him beyond the bounds allowed by the leaders of the Wesleyan Conference, for when he was about thirty years of age he corresponded with William Clowes and some other preachers of the Wesleyan body in reviving open-air religious services and camp meetings, or great gatherings for preaching and public worship. Thenceforward, in his younger days, he was in the midst of Methodism, and carried to very great lengths in America, were discomfited by the Conference, which in 1807 passed a resolution to the following effect:—

"It is our judgment that even supposing such meetings (camp meetings) to be lowest, they are highly improper in England, and likely to be productive of considerable mischief, and we disclaim all connection with them. This led to Mr. Bourne's separation from the Wesleyan Conference, and the establishment of the Primitive Methodist Connexion, the first class (or local society) of which was formed at Stanley, in Staffordshire, in 1810. This body, which in 1811 had two preachers and about 200 members, has since grown to 332 preachers, and 7842 members. In 1833 the connexion numbered 1789 chapels and 3565 rented rooms, with 566 paid travelling preachers, and 9394 local preachers. The members at the same time had reached 106,965. The discipline of the Primitive or Wesleyan Methodist Connexion includes chiefly in the free admission of laymen to the conference of the former body.
archiepiscopal patronage," in great depression of spirits, Bowles made a tour through the north of England, Scotland, and some parts of the continent; and it was during this tour that he composed the 'Sonnets' which first made him known as a poet. The 'Sonnets' were intended for his own solace, and were not even committed to paper; but in 1789, when he had been some time back in England, it occurred to him, as he was passing through Bath on his way to Oxford, to send them to his friend Mr. Grattwell, and have them printed. Accordingly, he got Mr. Grattwell, printer of a Bath newspaper, to strike off a hundred copies 4to, under the title of 'Fourteen Sonnets,' written chiefly on Picturesque Spots during a Journey. The copies were sent to Bowles, and by the end of the next month after the publication he received a letter from Mr. Grattwell, informing him that the 100 copies were all sold, and that he could have sold 500. Much encouraged (his father was just dead, and his mother was in somewhat reduced circumstances), he printed a second edition of 500, adding some new sonnets; and some time afterwards a third edition of 750 was called for.

It is curious now, looking back, to think that in a year or two, when France was in the throes of revolution, the publication from a provincial press of 'Fourteen Sonnets,' by a young clergyman disappointed in love, should have been an event of any consequence in England; and yet so it was. A new literary spirit, and new notions of poetry, were making their appearance. The sonnet was received, as something fresh and natural, even if but feeble, after the strong and fine artificialities, as they are called, of Dryden, Pope, and their followers. Bowles's sonnets came at the paper moment. Other young men of presenting age, in that year or two, had appeared, and all new vein; but, both as the pupil of the Warton's and by reason of his natural susceptibility, Bowles was fitted to take the lead. His sonnets were read and read again by all academic young men of taste and spirit; and children of his parish, after the first copies, kept out of school, and had to be sent for. Bowles was known, Southey, and Lovell. "I had just entered on my seventeenth year," says Coleridge, when the sonnets of Mr. Bowles, twenty-one in number (this was the second edition), and just then published in a quarto pamphlet, were first made known to him. Coleridge said, "I do not recall good verses published by us [that is, Christ's Hospital] for the University. As my school finances did not permit me to purchase copies, I made, within less than a year and a half, more than forty transcriptions, as the best presents I could offer to those who had the same interest as myself, and with almost equal delight did I receive the three or four following publications of the same author." These "three or four following publications" of Bowles were short copies of verses on occasional subjects. They were published in 1788, 1790, and 1791. Thus in 1789 were published "Verses to John Howard on his 'State of Prisons and Lazarettos,'" and in 1790 verses 'On the grave of Howard.' In these, although not so conspicuously as in the 'Sonnets,' a tender spirit and sensibility is displayed. It is not far less artificial than bad till that time been usual in poems. In short, though the revolution in British poetry had already broken forth in Cowper and Burns, and though it was to be completed in Wordsworth and Coleridge, Bowles's 'Sonnets' and other pieces, published in 1789 and the following years, were perhaps the first conscious inuition of the new principles. Wordsworth and Coleridge soon proclaimed and illustrated them with greater power of genius; but all their efforts were not with that kind of dithyrambic allegiance to Bowles as their titular patriarch.

Hardly foreseeing all this, Bowles left Oxford finally in 1792, having taken his degree, and devoted himself to the duties of his profession. From an humble curey in Wiltshire, he ascended by steps; and at the age of twenty-nine was living in the same county, and afterwards to another in Gloucestershire. In 1787 he married a daughter of the Rev. Dr. Wake, prebendary of Westminster. In 1803 he obtained the living of Great Bedwyn. Specimens of his poetry, which he published in 1806, included the long-awaited patronage of Archbishop Moore at last visited him in the shape of a preferment to the valuable living of Bremhill in Wiltshire. Bowles was then forty-three years of age; but he continued to reside in his picturesque county, and did not die till he was in the remaining forty-five years of his long life, discharging the duties of his parish in such a manner as to win the affection of his parochioners, varying his theological readings and his ecclesiastical business with continued exercises in literature, receiving visits from his friends, and happy in what he considered "the inestimable advantage of the social intercourse of such a family as that of Bowood" (Lord Lansdowne). Subsequent ecclesiastical preferments, which did not interfere with the quiet tenantry of his life at the rectory of Bremhill, were, his appointment in 1818, to be chaplain to the prince regent, and his appointment in 1828 to be canon of Salisbury cathedral.

But Bowles's life was not contented with issuing fresh editions of his 'Sonnets' and early poems (an eighth edition of the 'Sonnets' appeared in 1829), and with adding a few occasional pieces to the collection. In 1804 he published his longest poem, entitled 'The Spirit of Discovery,' in six books of blank verse, and followed it in the next two years with works in 10 vols. in 1807. These two publications, together with his general fame as a writer of sonnets, were the ground for the well-known attack upon him by Byron's 'English Bards and Scotch Reviewers.' Notwithstanding Byron's onslaught, Bowles, like Coleridge and Wordsworth, retained his reputation, and went on republishing old and producing new poems. He and Byron met in a friendly way at Roger's in 1812; and Byron in later life made amends for his satire by speaking of him with respect. Omitting minor productions, the following is a list of Bowles's poetical works subsequent to the 'Spirit of Discovery':—"The Missionary of the Andes," in six books of heroic verse, published in 1815; "the Grave of the Last Saxton, a Legend of the Battle of Flodden," in four books of blank verse, published in 1817; "Bowles," a dramatical didactic poem in blank verse, published in 1829; "St. John in Patmos," a blank verse poem of considerable length, first published anonymously; "On Scenes and Shadows of Days Departed," a series of poems with prose annotations, first published in 1837, in the author's seventieth year; and "The Village Verse-Book," published in the same year, and consisting of simple hymns composed by him for the use of his parishioners. After this, Bowles did not publish much. Nor had any of his poems since "The Missionary," which is considered on the whole the best of his large works, greatly added to his reputation. In all of them were discerned the same free taste, the same sensibility to the finer beauties of natural life, the same pathos, the same poetical faculty, and the same power of cultural expression which had distinguished his first sonnets; but it was felt on the whole that he was a kind of feebler Wordsworth, whose poetry, so long as he chose to write any, was rather to be received with respect and dipped into at leisure than eagerly read and appreciated.

But the whole virtue of Bowles's life did not lie in his poems. He was also a very busy prose-writer. If the list of his prose-writings is extended, it is found that he proved considerable versatility on the part of the author. The "Pope and Bowles Controversy," which lasted from 1819 to 1828, if indeed it may not date from 1807, when Bowles's edition of Pope was published, has a permanent interest in one respect. It is true that neither his "Pope," nor his "Bowles," nor the "Controversy," is of the value of his verse; but it is a complete prose, between the old or eighteenth century school of English poetry and the so-called new or nineteenth century school. Bowles, while doing justice as he thought to Pope's true excellences, had made some reflections on his moral character, tending to depreciate it; and he had, in an appended essay 'On the Poetical Character of Pope,' laid down this proposition, as determining the comparatively inferior rank of certain portions of Pope's poetry. — All images drawn from beauty are more beautiful and sublime than images drawn from art, and are therefore more poetical; and in like manner the passions of the human heart, which belong to nature in general, are per se more adapted to the higher species of poetry than those of the intellect. In 1828, Bowles published "The Principles," &c. which is a work of the right of the world to the artificial to furnish images to poetry, and instanced "ships" and the like to prove how beautiful and poetical such images might be. The work is a complete justification of Bowles's first distinct contradiction to Bowles's critical theory of poetry. Campbell vigorously defended the right of the world of the artificial to furnish images to poetry, and instanced "ships" and the like to prove how beautiful and poetical such images might be. The work is a complete justification of Bowles's first distinct contradiction to Bowles's critical theory of poetry. Campbell vigorously defended the right of the world of the artificial to furnish images to poetry, and instanced "ships" and the like to prove how beautiful and poetical such images might be.

letters for Pope and Campbell against Bowles, to which also Bowles replied. Other critics, including Octavius Gil- christ and the "Quarterly Review," took up the question on Coleridge's behalf and eventually met them one after an-
other, restating his real views in opposition to what he con-
sidered misrepresentations of them, and supporting these views by reasonings and examinations of the reasonings and
effects of his antagonists. For some time he stood alone; but
by the time the "Black Band" came to his assistance, and maintained that on the whole he had had the
best of the argument. This view is now pretty generally
acquiesced in. Bowles never said anything so absurd as that Poetic
rhetoric broke at his feet; or perhaps some
who have engaged in the contro-
versy; he only laid down some critical canons determining the kind of much of Pope's poetry, as compared with higher kinds, of which fine examples were found, he said, in other poets.

BRAVE, BRAKELINCH, [Devoures],
BRAGANTIA, a genus of plants belonging to the natural order Aristolochiaceae. One of the species, B. somnifera,
is said by Dr. Horsfield to be intensely bitter; and to be used as a medicine.

BRACHIODar, [devoures],

BRAY, Edward WELLAKE, F.S.A., a laborious and accurate topographer, was born in London (in the parish of Lene) Sep., 1772. He was apprenticed to one of the eminent practitioners of the

art of enamelling, but having from an early age been strongly
addicted to literary pursuits, he gradually abandoned that
business as a means of life, and devoted himself, a few years
earlier than his contemporaries, to the more congenial
of professional literature. His acquaintance with Mr. Britton
[Burnet, John, S. 2.] had commenced before the expiration
of his apprenticeship, and he also being desirous of exchanging a
service occupation for the pursuits of literature and the
fine arts, he was introduced to the editor of the London Literary
undertakings of a minor description, until they united in
projecting and in producing the well-known work on which their reputation was originally founded—"The Beauties of
England and Wales," and "A Tour in England," which was
produced by them. This work greatly contributed to extend and gratify
the seat for topographical history by which the early part of
the 19th century was so remarkably characterised. The
illustrations, chiefly copper-plate engravings, directed also
by Mr. Britton, were in numbers, and the beauty of the architectural
eminent of our architectural and landscape draughtsmen and
engravers became qualified for the execution of works of a
higher grade in art. Mr. Brayley himself contributed also
to the progress of the fine arts in a sister direction. Having
become acquainted with the late Henry Bone, R.A., when
that artist was endeavouring to elevate painting in enamel to
the position it subsequently acquired in his bands, as an
integral and a legitimate branch of accepted pictorial art, he
was interested in bringing about this change in art, and
by means of the plate engravers, and the enamellers of the
life, and contributed to the care with which he introduced
into country history—"The Beauties of England," and in his subsequent
works—the more characteristic or interesting features of the
natural history of the localities described. He acquired also
some of that character of occupation which in after-life he applied to good purpose in his archaeological researches, in taking casts of sculptured ornamental impressions of inscriptions, rubbings of engraved monuments from classical statues, and lithographs of those literary
and topographical works generally, that though there were better
geographers and historians, better architectural and decorative
antiquaries, better heralds, critics in art, and bibliographers
there were probably few of his contemporaries—certainly
few of them who could match him in the extent and extent of
the whole of the knowledge of the subjects of all these branches
of literature and archæology to which is termed Topography, i.

has his best work, was also his last. 'The Topographical
History of the County of Surrey, which he composed and
published at the ages of sixty-eight and seventy-six
during which period the history of the places and objects
described was diligently and critically investigated in the
localities themselves in very many journeys into the country.
For a year or two prior to his decease, gradually increasing
weakness impeded or averted his going to the scenes
which is him by members of his family, but his intellectual
powers remained unimpaired until the period of his death, which
was occasioned by the consecutive fever of cholera, on the 3rd of September 1864, in the ninety-seventh year of his
life, 'in his Paradise,' as he had himself named it. Mr. Brayley
became a Fellow of the Society of Antiquaries of London, in
1834, at the age of forty-six. He was in the prime of his
life, lived to be respected and beloved, and as long as
those years, his surviving children are the eldest son and
daughter.

The following is a list of Mr. Brayley's principal works and
contributions to literature:

1. A Picturesque Tour through the Principal Parts of Yorks
terne and Derbyshire, by the late Mr. Edward Dayes; with
illustrative Notes by E. W. Brayley, 1805: second edition,
and additional notes, 1825.

2. Views Illustrative of the Works of Robert Blomefield,
sculptor to His Britannic Majesty. prefixed to a Memoir of the
Poet's Life, 1806.

3. Copper: illustrated by a Series of Views; accompanied
with Copious Descriptions, and a Brief Sketch of the Poet's
Life, 1810.

4. Descriptions of Places represented in Middlesex, and
illustrative of the History of that County, with Notices and
Biographical Memoirs of the Abbots and Deans of Westminster,
1818-23.

5. The Beauties of England and Wales; comprising some
original delineations, topographical, historical, and descriptive,
of each County, 1810-14.

6. The British Atlas; comprising a series of Maps of all the
English and Welsh Counties; also Plans of Cities and Principal
Towns, 1810.

8. The History of the Ancient Palace and late Houses of Parlia-
ment at Westminster, 1830.

9. Quoted Herdman:--'A Concise Account, Historical and Descriptive, of Lambeth Palace,' 1806.

10. BREAD, DISEASES OF. [Saxony, S. 2.]

BRIDGES. The requirements of railways have led, within
the last few years, not only to the erection of stone and brick
bridges and viaducts, but to the abandonment of the old en-
system, but to a far more extensive use of iron, and the
adoption, in conjunction with its employment, of new con-
structive principles, as well as the bolder, and often novel,
application of old principles already in general use. Of the
stone and brick bridge and viaduct, so long and often
fulsome as works of art, and interesting for their modes of con-
struction, as many of them are, we do not intend here to
speak. Our purpose is to notice some of those great iron
bridges which have been erected, either as temporary or newly
applied principles since the publication of the 'Penny Cyclo-
pedia' and 'Supplement.'

All the bridges we have to describe are applications of the
beam or girder. Crossing indifferently populous thorough-
fares, and navigable rivers and streams, as well as streams and
ways which commercial traffic seldom visits, the railway
bridge or viaduct must often be of wide span, and so
constructed as neither to impede traffic nor interfere with the
flora. By this, neither, the direction nor the level of the way can be
followed, and the space to be crossed must be left as much as possible
unbroken by divisions. The problem for the railway en-
gineer, therefore, was to span the widest area with the least
construction, a matter of course, with the object of economy,
both in cost and in material. The simplest form, was soon found to be
unsuitable. The earliest mode was to return to the most primitive.
One of the earliest artificial bridges, if not the very earliest, was no doubt
a beam or girder, —whether that was the trunk of a tree or a
permanent structure, laid across the stream or place to be
crossed, with its ends resting on the banks or on artificial
supports. And after the invention of the arch, the beam
continued to be used for bridges as well as for innumerable
other purposes. The engineer, as he formed his design, anticipated
the weakness of the beam, except within the narrow
limits, and various methods were invented for strengthening
it by the addition of diagonal and other bars or rods, tech-
nically known as bracings, stays, and trusses. Of these,
beams, girders, as they are called, the general principles and
applications, and the methods employed for determining
their strength, ample accounts will be found in 'The Penny
boys, pp. 144-178; and Matrasiles, Stenof, vol, 15, p. 8.

The principal varieties of braced girders which have been
adapted on account of their weight and stability, are the trellised, the
low-and-string, and the hollow-beam, or tubular: the application of
which will be sufficiently illustrated in the Crumlin
and the Boyne viaducts; the Chestrow and the Saltash;
the Newport and the Britannia; and the Victoria other
bridges. We wish to use a uniform style and scale of the
formulæ, applicable to almost every purpose on which he can
called to exercise his skill.

The principal varieties of braced girders which have been
adapted for railway bridges are the trellised, the low-
string, and the hollow-beam, or tubular: the application
of which will be sufficiently illustrated in the Crumlin
and the Boyne viaducts; the Chestrow and the Saltash;
the Newport and the Britannia; and the Victoria other
bridges. We wish to use a uniform style and scale of the
bridge in the Niagara Falls Bridge.

The Crumlin Viaduct was constructed from the designs
and under the superintendence of Mr. Britton, the engineer,
to carry the Newport Aberavon and Hereford line through
the valley of Crumlin, in South Wales, and to connect the
above line with that of the Tale Vale. With its approaches,
the bridge is a third of a mile long. The bridge itself con-
ists of seven spans, each of 160 feet long, the roadway
in the centre spans being at an elevation of 200 feet. The

M
The girders are composed of groups of thin cast-iron columns, each of 17 feet high by 1 foot in diameter, and arranged in tiers of fourteen columns each, cross-braced by wrought-iron ties and cast-iron struts. The central piers are 60 feet, by 30 feet at the base, tapering upwards 84 feet by 16, and contain the main span; they have no less than 540 wrought-iron ties. At the top of each pier is a triangular frame of cast-iron, upon which rest the ends of the main girders. The girders themselves are strengthened by a complete iron arch, wrought-iron arched, among which it would be impossible to explain clearly without diagrams, but which forms an admirable system of trellis trussing. There are four main girders to each span, to which six-inch planking is bolted for carrying the permanent way. The girders are of great size, and, from the extraordinary appearance, yet seems to be sufficiently strong not merely to support the heaviest traffic, but to withstand the most violent storms. It was opened in May, 1867.

Another admirable example of the trellis-girder bridge is the viaduct which carries the Dublin and Belfast Railway over the Boyne, near Drogheda, and of which Sir John McNeill was the engineer. This noble work consists of a centre span of 364 and two side spans of 188 feet each. The girders in the main span, as well as those above spring-ties is 90 feet. It was opened in April, 1856.

The High-Level Bridge, Newcastle-upon-Tyne.—Under Roof, 'Penny Cyclopedia,' vol. xx., p. 147, a cut and description are given of the simplest form of bow-and-string railway bridge. The advantage of such a bridge is that the main girders spring from the abutments, and each is divided into parts of about a-fifth of the whole, as illustrated by the line drawing. The connection of the principle to girders of wrought-iron is noticed. For carrying railways over spaces of unusual width, or at a very oblique angle, bridges of wrought-iron bow-and-string (or as they are by railway engineers so called bow-string) girders were early found to be peculiarly suitable. Other engineers, of an important character, it may be sufficient to mention an excellent one, which carries the North-Western Railway across the Regent's Canal, near the Camden-town stations. A bridge of this kind, by which the North London Railway crosses the Commercial-rod to Stepney; and one, of rather peculiar form, on the Gloucester and Birmingham Railway at Cheltenham. But by far the most magnificent bridge erected on the bow-string girder principle, is the High-level Bridge which unites the towns of Newcastle-upon-Tyne and Gateshead.

When the Newcastle and Berwick Railway was planned, it was felt that a junction with the Newcastle and Darlington line could be effectually only by the construction of a lofty bridge over the Tyne at Newcastle; because the banks of the river at that spot are very steep, and the general level of the railways would not permit of a crossing at a relatively small height above the water. It had long been wished by the proprietors of the line to have a high-level bridge, since the old bridge was adapted only for the low or water-side districts of Newcastle and Gateshead; and Mr. Robert Stephenson boldly designed a scheme which should meet this requirement, as well as the requirement of the railway companies. His plan was to have a double bridge, with a railway line over a common road. The railway companies and the town corporations assented; an Act was obtained; the works were actively commenced about the beginning of 1847; and the bridge was opened by the Queen in person in September, 1849.

The width of the river at this spot is 615 feet; but from the high ground in Gateshead to that in Newcastle the distance is above 1400 feet. The bridge is of six spans, each of 1400 feet, and is the longest of any wrought-iron bridge across the river, and one from each bank; besides minor piers to support the roadway on either side. The superstructure consists of two platforms, an upper, carrying three lines of rails; and a lower, which forms the public road. The lower platform is about 90 feet above the high-water level; the upper is 20 feet higher. Each span or bay of the bridge is crossed by four main cast-iron arched ribs, with horizontal tie-bars. These ribs are disposed in pairs,—the two inner ribs being each 170 feet apart, the space between them forming the carriage road; while between the inner and outer ribs is a space of six feet, which is used for foot passengers. The upper, or railway, platform rests upon the arches, the lower roadway being suspended from them by wrought-iron struts or girders. These struts or girders, which, when put together, give a span of 125 feet, with a rise of 18 feet. In some portions, the ribs are braced by horizontal and vertical bracing frames, while diagonal bracings are inserted in the spandrels, or spaces between the arches and the girders which carry the railway. On the tops of the spannel pillars, girders extend lengthwise, from which others stretch at right angles across the arches, the whole being supported by spandrel girders at least 100 feet in height. Mr. Stephenson at first proposed to meet the requirements of the Commissioners by erecting an iron bridge of two immense arches; but his plan proposed that the arches should be 100 feet high at the spring of the arches, and the Commissioners refused to permit it to be executed unless he raised the level so that the spring of the arches should be 100 feet above the water. As this would have compelled the height of the bridge to be 1400 feet, Mr. Stephenson abandoned his intention, and boldly resolved to cross the channel by a girder bridge. He found a site about a mile on the Caernarvon side of Telford's famous suspension bridge, which was admirably adapted for the kind of structure he contemplated,—the approach to it being on an island, and a strait, or a mere point, about mid-channel a rocky island, which would afford an excellent foundation for a central pier.

The space to be crossed was 1100 feet wide, and each pier of the bridge was, therefore, 550 feet long.

It was necessary not only to provide that the masonry beams, as yet unapproached in bulk, which were to be suspended at an altitude of a hundred feet above high-water, should be sufficiently strong to sustain their own immense weight, and may train in rapid motion, but that they should be able to withstand the action of the fierce gales which are frequent in this locality. It was deemed advisable, therefore, to institute an extended series of elaborate and costly experiments and investigations on the strength of iron, and the manner in which it might be arranged, so as most to conduct to the strength and rigidity of the bridge. These experiments, which were conducted by Mr. William Fairbairn and Mr. Eaton Hodgkinson, called into exercise a union of the highest mechanical and mathematical skill, and not merely sufficed for the immediate purpose, but have afforded a sure basis for the labours of succeeding engineers. The result was the demonstration that the greatest amount of strength would be obtained by giving the masonry beam a peculiar form, and a width which may train in rapid motion, but that they should be able to withstand the action of the fierce gales which are frequent in this locality. It was deemed advisable, therefore, to institute an extended series of elaborate and costly experiments and investigations on the strength of iron, and the manner in which it might be arranged, so as most to conduct to the strength and rigidity of the bridge. These experiments, which were conducted by Mr. William Fairbairn and Mr. Eaton Hodgkinson, called into exercise a union of the highest mechanical and mathematical skill, and not merely sufficed for the immediate purpose, but have afforded a sure basis for the labours of succeeding engineers. The result was the demonstration that the greatest amount of strength would be obtained by giving the masonry beam a peculiar form, and a width which is necessary to the train of the great hollow beams, it was decided to have two or upwards of a quarter of a mile long, placed side by side, one for the north, the other for the south traffic, each of which should rest upon abutments, the intermediate portions being supported across the strait by three massive and lofty stone piers or towers.

The bridge, then, as finally constructed, consists of four spans,—two principal spans, of 460 feet each, which are over the water, and two smaller ones, of 330 feet each, which are over the land. The central, or Britannia Tower, is 727 feet 6 inches above the level of the Low Mersey, and is built on a block of the Monmouthshire sandstone, at the base is 62 feet by 62 (the pedestal of the Monument, being 20 feet square), and it tapers gently to 55 feet by 4 at which height it is 50 feet high. There are 13 arches of the tower, of which 11 are of 144 feet span, and rise to the height of 184 feet above the low water mark; and 2 in near all 20,000 tons; and 387 tons of iron cast from 150 to 200 tons; of wrought-iron girders are built into it. The east and west, or land, towers are similar in general construction to the Britannia Tower, but somewhat smaller, and only 190 feet high; they stand on a base 160 feet by 160 feet, and each tower contains 145,682 tons of masonry and 444,983 tons of wrought-iron, in all near 20,000 tons; and 387 tons of iron cast from 150 to 200 tons; of wrought-iron girders are built into it. The east and west, or Caernarvonshire and Anglesey abutments, are situated inland, at a distance of 300 feet from the strait, and connected with it by a causeway forming a link of the bridge.
est and west towers respectively, and are constructed of massive masonry.

Although the tubes form two continuous hollow beams or tubes they consist in fact of eight pieces, four to each tube, which are joined end to end at the piers. The height of the tubes is 30 feet at the Britannia tower, and diminishes to about 23 feet at the abutments; the upper surface being slightly arched, but the lower horizontal. The clear internal height varies from about 19 feet to 26 feet. The external width is nearly 15 feet, and the internal about 14. The sides, top, and bottom are all formed of wrought-iron boiler plates, varying from 0 to 12 feet in length, from 3 to 20 inches in width, and from 1 to 2 inches in thickness. The metal is wrought iron of the best quality (some of which weigh nearly 7 cwt. each) are laid lengthwise in the top and bottom, but vertically in the sides of the tube. The largest plates are in the bottom, where they are arranged in a double layer. The plates are joined together by rivets; and are stiffened and strengthened at the joints by T-shaped iron, both inside and out, which form vertical bars up the sides, at distances of two feet apart. The connection of the top and bottom with the sides is made more substantial by triangular gusset-pieces riveted in at the corners. The plates in the entire structure are almost incomparably numerous; they are placed four inches apart in the top and bottom, and three inches apart in the sides. They are rather more than 1 inch in diameter, and were driven red-hot into the rivet-holes, and then left to cool for the metal to contract. The metal thickness is nearly three-quarters of an inch; and the bottom and top have proved hard to be pointed out: it is almost unnecessary to mention indeed as an illustration that it is to having been constructed on this principle, that the Lewisham steamer owes the enormous strength which has been so severely tested in the course of its prolonged launch.

The Conway Tubular bridge is a repetition on a smaller scale of the Britannia bridge, but was constructed before it; and was, in all probability, the very first thoroughly tested in the smaller structure before it was applied in the larger.

The Conway bridge consists of a single span of 400 feet clear, the platform of the tube being only 18 feet above the high-water level. The first stone of the masonry was laid in June, 1846; and the bridge was completed and opened for traffic in 1850.

Victoria Bridge, Canada.—A more remarkable bridge as to size and in many other respects than even that over the Menai Strait of a similar superstructure is the Victoria bridge of the Grand Trunk of Canada railway, which is in course of construction across the St. Lawrence, and is expected to be completed in 1860. From shore to shore of the St. Lawrence, the Victoria bridge will be nearly two miles in length, being about five and a half times the whole length of the Britannia bridge. The foundation of the Victoria bridge is on a larger scale than that of the Britannia bridge, the depth below the summer level of the St. Lawrence. The length of the bridge between the abutments is 8000 feet. The engineer is Mr. M. Ross.

Chaputon Bridge.—In this bridge, which carries the South Wales railway across the river Wye, near Chepstow, Mr. Brunel has employed two kinds of trussed girders, and also applied the rigid suspension principle. In one portion of the bridge wrought-iron girders 100 feet in span, and of the ordinary form, rest on cast-iron columns; while in the other portion, which is 305 feet in span, the trussed girders are sustained by chains, the tension of which is resisted not, as in an ordinary suspension bridge, by being fixed to the ground at either end, but by attachment to a horizontal wrought-iron column or strut, 9 feet in diameter and 10 feet in height. These are the belts and ties which rest on the towers at the ends of the bridge. The chain consists of three straight links only—its rigid form being maintained, and the flexure of the horizontal cords being supplied by the tension of the chains. The deck of the bridge is formed by 12 beams riveted to 8 wrought-iron columns. The girders which carry the roadway have only two points of suspension, one at each end of the bridge, and they are suspended from an arch formed by wrought-iron columns. The transverse girders are light, of 87 feet above the ordinary low-water level, but owing to the remarkable rise of tide here, only 46 feet above high-water. The towers at the ends of the bridge present no peculiar features, but the middle one rests upon a pier formed by six enormous cast-iron
cylinders which pass through 50 feet of soil to the solid rock beneath. They were sunk to their positions by the removal of the mud, and the pressure of their weight, (in the manner of Roman swivelled trees,) forced the cylinders into the rock. A somewhat similar combination of the rigid suspension principle, with the tubular form, is being carried out in Mr. Brunel's Royal Albert Bridge, at Saltash, near Plymouth, which is intended to carry the Cornish railway across the river. The bridge is to consist of two sections, connected by a Meeth Downderry line. The total length of this bridge is 2200 feet, the principal spans are each 455 feet, and the height of the railway above high-water level is 100 feet. The centre tower is built of solid granite to a height of 12 feet above high-water mark, upon this rest four octagonal cast-iron columns which carry the standards upon which one end of each tube rests; this tower rises to a height of 240 feet above the foundations.

The principal side piers are of solid masonry, and carry the bed plates and rollers upon which rest the other ends of the tubes, and which permit their free expansion or contraction under the influence of variations of temperature. The tubes are similar in principle to those of the Britannia bridge, and like the latter, after being constructed at the river side were floated out on the river, and then placed on the towers, and thence gradually lifted by hydraulic pressure to their ultimate position.

Niagara Falls Suspension Railway Bridge. The most remarkable application of the suspension principle, for railway purposes, has been made in the bridge constructed across the Niagara river, by Mr. J. A. Roebling, in order to carry the railway, and also the ordinary carriage and passenger traffic across that river. The space to be crossed was about 820 feet, and the level above the water 24 feet. From the nature of the locality it was necessary that the bridge should consist of a single arch or span, whilst the erection of scaffolding or the floating of portions of the structure would have been impracticable. Hence a suspension bridge appeared to be the only available form of structure. But any other than rigid bridges had been shown to be unsuitable for railways, and it became necessary to overcome the flexibility inherent in suspension bridges of the ordinary kind. This the engineer has successfully accomplished, and the bridge which links the British possessions with the United States is, confessedly, one of the most remarkable achievements in modern engineering. The main beam, slightly curved in form, is 25 feet wide at the bottom, and 24 feet at its top, 18 feet high, and 821 feet long from the centres of the towers. Along the bottom of the ordinary passenger traffic is carried; along the top runs the railway. Separate systems of wire cables, two sets in each span, support these two different types of roadways, which are constructed of timber beams. The roadways are connected by double trusses so arranged that their resistance acts in opposite directions, upwards as well as downwards. The beams of the two floors are connected by posts, which serve to transmit the depressive action of loads from one floor to the other. The posts are trussed together by diagonal rods. By these simple arrangements in combination with the tubular form of the bridge, a considerable increase of rigidity is obtained. To maintain horizontal stability the upper cables are braced laterally, and they are diagonal stays of wire above and below the floors. Fifty-six stays from the lower floor to the ends of the bridge are strung and anchored in the rocks. For the secure anchorage of the cables, expansion and contraction from variation of temperature, high winds, &c., it is needless to say careful provision is made. The railway traffic passes along the centre of the upper floor, the common wagon traffic along each side of the lower floor. The anchorage was commenced in September, 1852, the bridge was opened for traffic in March, 1855. The total cost was under 400,000 dollars. The bridge answers its purpose perfectly; but it must not be supposed that this has proved the suitability of the suspension principle for railway purposes in all circumstances. In this case the river being unnavigable, the engineer has been enabled to obtain stable rigidity by the use of an extended series of stays below the roadway, securely fastened to the piers by chains and to the bed of course by immovable piers, and additional cases. And although by the judicious application of the tubular form, and the use of a happy combination of trusses, girders, stays and weights, a remarkable amount of rigidity has been obtained, it is yet considered unsuitable to be trusted with the traffic of more than three miles an hour. At that rate when a train of 326 tons is passing over it, the bridge only can bear the exten- sion of 10 inches, and the roadway assumes its original shape immediately the train has passed.

Foundations of Bridges. To our notice of new principles applied in constructing the superstructure of bridges, it may be added, that whatever importance may be attached to the new expedients adopted in forming the foundations. Until recently, in order to build the foundations of piers and abutments of a bridge under water, one of two plans was adopted: the first was to construct the pier, using for the purpose of a cairn, a wooden dome, or wooden dome, tight enclosure from which the water was pumped out, to allow a firm and dry foundation to be laid,—this plan was to plan adopted at London and Waterloo bridges and in many other bridges of an important character; the other, and much less costly, though less stable method, was to surround the platform on which the foundation of the pier was built with water-tight sides, and thus make a large water-tight basin, or caisson, the sides of which, when the platform was sunk to its proper level could be detached, the bottom or stage working as a foundation—this was the method used in constructing the piers of the old Westminster bridge. (Coffin's Penny Cyclopaedia, vol. vii. p. 394.) Coffin-dam and caisson were of course modified in form according to situation, and the method of construction according to the views of individual engineers; but wherever used they have been the same principle. A more economical and less tedious system, one which should be equally durable, has long been desirous of being evolved, but had not only the approval of engineers, but also the approval of the public. A plan, which was uniformly carried out in practice, as far as construction goes, with which there seems no reason to doubt their permanent stability, has been adopted both in this country and on the continent, where coffin-dam and saddle have been dispensed with. Piles and concrete, cased in this
have been used in Brussel's railway bridge at Chepstow described above, and in various parts of the continent; and the same materials may, according to requirement, as in the bridge at Ronen, and the bridges of Jena, Austerlitz, Alma, and Victoria over the Seine. Cast-iron as an outer casing, in various forms, and with concrete or other materials as the filling, has been used in England and Ireland in numerous instances. In the Alma bridge over the Seine, having a length of 470 feet and seven arches, the piers are founded on piles driven into the bed of the river over the whole area. The space between the piles is filled in with concrete and rough stones, the whole is enclosed by wooden sheet-plighting, and is protected from the river by high rough stones. The Suspension bridge at Chelsea was built by enclosing the area by piles and iron plates, driving wooden piles at short distances over the whole space, and filling in with concrete, and of course without using either cast-iron or casings; and the new bridge at Westminster is being built by the same engineer, Mr. T. Page, on a similar principle. In the Town bridge and the Railway bridge recently erected alongside of each other at Rochester, the piers are supported solely by a number of cast-iron cylinders, filled with brick-work and concrete. A description of the methods adopted by Mr. Page at Westminster bridge, and by Mr. Hughes at the Rochester bridges, will serve to indicate sufficiently the direction taken by civil engineers in this branch of their practice. It is observed, by the writer, that the economy in cost, partly on that of saving in time, but chiefly perhaps in order to avoid the excessive obstruction of the water way which would have arisen from building a bridge of several arches close against one another, or when a still larger number of arches, the piers of which would not coincide in position with those of the new,—not to use coffers-dams in constructing the piers of the new Westminster bridge, the system proposed by the engineer, Mr. Page, was examined and approved of by the Bridge Commission. Mr. Page, which is being carried out as rapidly as circumstances permit, was to drive a number of bearing-piles over the whole area, to a sufficient depth in the clay, but to leave them standing at some considerable height above the gravel, as the base of the pier; to enclose the area between the piles and the gravel, with round hollow iron piles, and flat plates alternately, the former sustaining the latter by grooves, and all driven down to a sufficient depth; to dredge out in the spaces between the bearing-piles to the hard gravel; and to fill up all the spaces and area in the casing up to the level of the tops of the piles, with concrete made from Portland cement, which has the property of setting under water, the concrete being deposited through the water by means of shoots. The casing was previously tied together, across the intended pier, by iron bolts. This system of construction was to terminate at or near the low-water line. Blocks of granite were to be fixed over these piles, cemented, and in, and the whole to be levelled off to receive a heavy bed of granite capping, or rather base course, above which the pier would be continued in brickwork faced in granite, to finally support the building, as indicated in Plan. The works in course of execution are of course retarded by the rise of the tide; but otherwise, though below water, they are conducted above it, except as to the requisite inspection, the attachment of the iron ties, and the bond in similar cases where the diving-bell or the diving-dress is used.

The 145 bearing-piles in each pier of Westminster bridge are driven to an average depth of 29 feet 6 inches below low-water line. The piles, each 24 feet 8 inches in length, are driven 25 feet 9 inches below low water, and to make up the height, they are surrounded with sheet-iron slabs, which, consequently with the upper part of the round piles, are part of the casing. The bearing-piles are thus 22 feet below the average level of the casings of the old bridge, and the cast-iron piles and plates are respectively 10 feet 9 inches, 14 feet 9 inches, and 16 feet 9 inches below the low-water mark. The space external to the pier is intended to be provided by a solid mass or bank of concrete round the pier; this concrete when set forming a kind of artificial rock, which is found to be of the same durability as old iron. When this concrete a trench is dredged out to the clay, and it is proposed that it shall have a thickness of five or six feet; so that, should it endure, as the hardness and heaviness of the mass would make probable, the flat piles would be always underground, and at the junction of the floors of the piers could be no escape of the gravel. Mr. Page further proposes to dredge out the channel under the arch to a regular curve, commencing at three feet below low water at the piles, laying bare the clay at the centre, so as to give a low-water depth there, and allowing a certain superincumbent head in preparation to keep up the circulation of the stream of the tides, that the tendency would not be to scour at Westminster bridge, but that the first operation would rather be to fill up. The entire cost of constructing the foundations of Westminster bridge on Mr. Page's system is estimated at about 60,000£, less than by the employment of coffer-dams. A peculiarity in the construction of the new Westminster bridge is that, in order to save the usual expense of building a temporary wooden bridge, the new bridge is to be erected on its circuit form works on the site of an old one, only one half of the bridge—the western—is in the first instance to be built along side of the old structure, which is during its progress to be used for the ordinary traffic, the old bridge being then to be used for traffic, the old bridge is to be demolished, and the other, or eastern half of the new bridge erected on its site. This necessitates the construction of the piers, as well as of the bridge itself, in two parts, at intervals of time, and doubts have been expressed whether there are not in consequence likely to be unequal settlements in the completed structure. Mr. Page has, however, suggested arrangements for the formation of the piers, and for the introduction of peculiar bracings in the coupling together of the two parts of the superstructure which will afford sufficient provision for any inequalities of subsidence.

In the system of Mr. J. Hughes employed in forming the foundations of the Town and Railway bridges which cross the Medway side by side at Rochester, the piers are supported on cast-iron cylinders, which were sunk down to the hard chalk by using each cylinder as a diving-bell. A somewhat similar principle has been applied to other bridges, and there are different claims to the invention of the principle. In the Medway bridge the invention of M. L. Potts, the sinking of the cylinder was effected by the exhaustion of the air contained within it, but though that method has been adopted in some cases, it has not met with general success. Mr. Crewe proposes an extinguishing of the air by the blowing of hollow cylindrical piles through sand by means of compressed air, to M. Triger, who thus sank a shaft through a quicksand 66 feet thick, on the banks of the Loire. But the actual conversion of the cylinder into a diving-bell is, in which the workmen carry on their operations, the diving-bell then forming a part of the permanent structure, is an
extension of the principle which is due to the ingenuity of Mr. Britton.

The Railway and Town bridges are both borne on abutments at the banks, and two piers in the bed of the river. To sustain the abutment on the Strood side 30 hollow cylinders were used; for the Rochester abutment 12, and for each of the two piers 14, making in all 70 hollow cylindrical piles, each 7 feet in diameter. The piles are respectively 70 feet long and 17 feet wide, and the cylinders are set at distances of 9 feet apart lengthwise, and 10 feet transversely. The bed of the river was found by boring to be composed of clay, sand, and gravel, overlying hard chalk, which appeared at a depth of 44 feet below high-water level. On this hard chalk the cylinders were to be based. To reach it for the Strood pier a mass of hard stone, part of the foundation of the original wooden bridge, had to be first planed off, and this was done by exhaustion which was evidently impracticable here. To ensure a firm foundation workmen must excavate the stone, gravel, &c., in order to prepare a passage for the descent of the cylinders, and then to secure their stability fill them with brickwork as soon as they were in the positions they were ultimately to occupy.

The cylinders were in lengths of 9 feet each, the diameter as already mentioned being 7 feet. Operations were commenced by dropping cylinders, containing long pieces of hollow cylinder into a diving-bell, by secretly bolting to one end of it a wrought-iron cover. Through this cover were two cast-iron air-locks (or chambers bearing a certain resemblance to the locks of a canal), with air-tight flaps or doors, by means of which the workmen were admitted to the cylinder, the excavated materials were passed out, and the brick and concrete passed in. Separate cocks, one under the control of a workman inside, the other under the charge of a workman outside, permitted the water and the bricks to be sent in or out of the buckets outwards or inwards, the filling of the chamber with compressed air, &c. There were besides a great number of ingenious appliances for the convenience of the workmen and to facilitate the various operations, which it is not possible to describe here, but which are fully described and illustrated in Mr. Hughes's Memoir on the subject, and in the Supplement (1856) to Mr. Curgy's 'Encyclopedia of Civil Engineering.'

A substantial timber stage having been erected over the site of the pier, and steam-engines and air-pumps conveniently placed, the prepared cylinder was connected with an air-pump and with various apparatus was lowered to the proper position on the bed of the river. "The working of the water was commenced by means of the pumps, which, by means of the flap of one of the air-locks and the door of the other being closed, a few strokes compressed the air within the pile [or cylinder] sufficiently to seal the joints; and every subsequent stroke delivered an additional quantity, until the cylinder was sufficiently compressed to expel the outside water and to leave it bottom dry. Fifteen feet of water was cleared out in five minutes; and whilst the pumping continued the workmen passed through the air-locks to their respective stations; and as the excavations proceeded, the material, sent up in buckets, was discharged into lighters placed alongside. During the time of shallow water, the pile descended as rapidly as the excavations below would permit it; but when the water was deep, and the weight of the pile and elasticity of compressed air contained in it were nearly in equipoise, the excavation was carried down 14 inches below the edge of the pile, when it would at once descend through the whole space as soon as the pressure was removed."

('Curgy's Encyclopedia of Civil Engineering,' p. 1697.)

While the cylinder was thus sunk 9 feet, the cover, with the air-chambers, was lifted off, and another 9 feet length of cylinder was bolted on to the first, the air-locks being now fastened to the top of the upper cylinder. The air-pumps were again set in action, and when the pressure was repeated, the cylinder sank another 9 feet. These operations were repeated till the necessary depth had been reached, when the cylinders were filled with brickwork and concrete. In the Strood pier nine lengths of cylinder were placed on each side of the central pile, excepting the middle one, which, being left unchafed above it was surrounded by soft chalk; the third by Kentish rag stone; while about half of the fourth was above the bed of the river.

Furnishing the foundations of bridges, but more particularly of lighthouses, landing-stages, beacon-houses, breakwaters, and other structures which have to be based upon sand or soft ground, hollow cast-iron screw-piles, the invention of which has been the subject of much attention, have been used in the above structures. These piles have the lower end converted into an anchor-screw, which enables the pile to be screwed with great facility through shingle, sand, &c.; while the upper part of the worm may be expanded into a disc, varying in breadth according to the character of the soil, and the height of the piles greatly the firmness of its hold. The value of these screw-piles is very great in situations where the loose sandy soil is incapable of supporting any solid structure, or where the action of the waves quickly undermines any work based on ordinary piles.

BREDARY. [Electio, S. 2.]
BREDY. [Morele.]
BREE. [No slip.]
BRIEL. [Le Bresson, W.]
BRITANY. [Britagne.]

BRITTON, JOHN, was born July 7, 1777, at Kingston St. Michael, near Chippenham, Wiltshire, where his father was a small farmer, and kept a vintners shop. His parents dying early, he was received as a servant by an uncle in London, who after a while apprenticed him to a wine-merchant. After having served six years, his health gave way, and his master agreed to cancel his indentures. Young Britton then returned to Chippenham, and from his early acquirements in arithmetical instruction, and during his apprenticeship he had become extremely fond of reading, but his reading was dawdling and aimless. On reaching manhood he was still undecided, and his mind quite unformed. At the close of his apprenticeship he was to have set out for India, but without any definite permit. For some years he had to struggle hard with poverty, and was driven to a variety of shifts to earn a livelihood. Among other things, he engaged himself for a time as a servant in housekeeping, and in the course of a few years he collected the sound title of Eledophnikos. During this unsettled course of life he formed the acquaintance of various persons connected with the humbler walks of literature, and he was induced to embark in a small way on authorship himself, by a comparative success of some sort which are in that line, and at length ventured on writing an 'Account of the Surprising Adventures of Pizarro.' Some short notices which he prepared for the 'Sporting Magazine' brought him acquainted with Mr. Whible, its publisher, and to the connection thus formed was afterwards added the pleasing title of a correspondent of the 'British Magazine.' After a time Mr. Whible solicited Mr. Britton to write for the 'Account of the Surprising Adventures of Pizarro,' and this, after a time, led him into the career of a writer of travel...
antiquities. It would occupy too much space to enumerate its many publications, which in his own chronological list, he places in his 'Life' in an alphabetical arrangement of seven distinct productions. The most important of them is the 'Cathedral Antiquities of England,' a magnificent work, which was commenced in 1814 by the publication of a detached form of the 'Antiquities of Salisbury Cathedral,' and completed in a series of articles in 'The Builder,' and of the entire cathedrals of England. In its completed form the 'Cathedral Antiquities' occupies 14 vols. fol. and 4to, 1814-35, with upwards of 300 highly-finished steel-engravings.

The production of these works was carried on throughout the whole of the author's life, and, as he had retired, some of the artists working in his own house, and being trained to the work by himself; and the facility he thus acquired in the production of this class of publications led to the preparation of many other works of a similar kind. Among the illustrated works of which he was either author or editor may be named—an 'Historical Account of Corsham House,' 1806; the 'Fine Arts of the English School,' 4to, 1812; 'Historical Account of Redcliffe Chuch,' 4to, 1813; 'Illustrations of Ponthill Abbey,' 1823; 'Historical Account of Bath Abbey Church,' 1825; the 'Public Buildings of London, from drawings by A. Pugin,' 2 vols. royal 8vo, 1825-26; 'Architectural Antiquities of Norman, drawn by A. Pugin,' 1825-27; 'Pictoresque Antiquities of English Cities,' 4to, 1830; 'A History of Architecture,' 4to, 1831-32; 'Architectural Antiquities of the Middle Ages,' 4to, 1832-38; 'A History, &c., of the Ancient Palace and Houses of Parliament at Westminster,' partly with E. W. Brayley, 8vo, 1834-36; 'Historical Account of the most admired edifices in the Countries of the British Isles,' 4to, 1842; &c. &c. But besides these Mr. Britton wrote on many subjects connected with general literature, either as distinct works or as contributions to literary journals, &c. In biography he published in 1846 a 'Biography of an Aubrey,' and in 1848 an essay entitled 'The Authorship of the Letters of Junius Elucidat, including a Biographical Memoir of Colonel Barré, M.P.' Mr. Britton wrote the articles 'Avehny,' 'Stonebenge,' and 'Tomnillus,' for the 'Fenny Cyclopedia.'

In another friend, Mr. Britton gave the veteran author a dinner on his retirement from the active, permitted of his calling; and it being determined to mark their esteem for him by a permanent testimonial, a social gathering called the 'Britton Club' was organised to carry out the project. The form of the testimonial, at Mr. Britton's own suggestion, it was eventually agreed should be an 'Antohography,' which he was to prepare and to print with the testitual funds. Despite of his advanced age, Mr. Britton completed his task; and several of the parts of his 'Antohography' were published, but he died before the work was completed, January 10, 1857.

Mr. Britton was not a man of marked originality or great mental power, but as a careful and diligent writer in a branch of his great interest, which he cultivated with indefatigable industry, the antiquaries, he did excellent service in calling the attention of the educated public to the long-neglected topographical and architectural antiquities of England; and there can be little doubt that his elegantly-illustrated works have been a chief exciting cause in bringing about the improved state of public feeling with reference to our national antiquities. The career of Mr. Britton was moreover an admirable illustration, as he himself describes it, "of what may be effected by zeal and industry, with moderate talents, and without academic learning."

BROCKVILLE. [Canada, S. 2.]
BROMAL [Chemistry, S. 1.]
BROMLEY. [Yorkshire.]
BROMLEY, ABBOTS. [Staffordshire.]
BROMUS, a genus of plants belonging to the natural order Gramineae, and the tribe Festucae. It has unequal many-flowered herbaceous glumes, the lower being 1-nerved, the stipules 3-nerved, and the leaves divided half way down. The species are generally known under the name of Brome-grass, but 'a mnemonic, and in the botanical dictionaries of those days, and expressed.

The outer palea short, (annually) founded on three stems below the tip. The styles below the summit of the fruticulat. The sheaths of the leaves divided half way down.

The species are generally known under the name of Brome-grass, but "a mnemonic, and in the botanical dictionaries of those days, and expressed.

B. erectus has an erect stem two or three feet high, and grows on dry sandy and chalky soils. It is known from the other species by the outer pales being indistinctly 7-nerved and one-third longer than the smaller glume. B. esser has its outer palea hairy and 5- to 7-ribbed, with the leaves broad and hairy. The stem reaches a height of four or five feet. It grows in damp woods and thickets.

B. sterilis is a common plant in waste places, and is known by its outer pales having 7 distinct equidistant ribs. It has large flat broad pinnate leaves, and a stem from one to two feet high. It grows in waste places.

B. distans is remarkable for its erect panicle. It is a rare plant.

Some of the species, as B. purgans and B. catharticus, are purgative, whilst B. molotis is said to possess poisonous properties.
journeys and labours to acquaint himself with the best productions and masterpieces which would alone have sufficed to occupy any ordinary man. The results of his long experience appeared in 1840 in his "Traité des Arts Céramiques." And carrying out his earliest researches on enamelling, he revived at Sévres the almost lost art of painting on glass. He found time, however, to share in the discussions of the Institute, and in promoting the interests of science, and the views of scientific inquirers. He died on the 14th of October, 1847.

Broumont was a foreign member of the Geological Society of London, and other learned societies, and his writings are to be found in the "Mémoires de l'Académie des Sciences," "Annales des Mines," 'Annales de Chemie,' and "Annales des Sciences Naturelles.

Many have been published in a separate form. Among them 'Essai d'une Classification des Regne Animal en quatre Classes,' 1823; 'De l'Imitation de la nécrophile des Roches métamorphiques,' 1813; 'Mémoire sur les corps organiques fossilisés nommés Tribolites,' 1814; 'Histoire Naturelle des Crustacés fossiles sous les Rapports zoologiques et géologiques,' 4to, 1822 (jointly with Desmarest); 'Introduction à la Minéralogie,' 8vo, 1823; 'Tableau des Terres qui compose l'Encyclopédie du Globe,' 8vo, 1829; 'Premier Mémoire sur les Kaolins, on Argiles à Porcelaine,' 4to, 1830; 'Second Mémoire sur la Naïlre et l'Utilisation des Argile,' 4to, 1841.

(1818 - 1847)

BRONTÉ, CHARLOTTE (Mrs. Nicholls, better known by her pseudonym Currer Bell), was born April 20th, 1816, at the parsonage of Branego, near Haworth, West Riding of Yorkshire, of which her father, the Rev. Patrick Bronté, had then the living. He afterwards held the living of Haworth, also in the West Riding, about four miles from Keighley. Mr. Bronté removed from Thornton to Haworth, February 12th, 1820. Charlotte Bronté was born at Haworth in February, 1819, went to Brussels, in order, by acquiring a better knowledge of the French language than they already possessed, to qualify themselves for keeping a school. On the 11th of July, 1831, the end of her course, it was thought necessary to return to Haworth. Emily Bronté remained at home, but Charlotte returned to Brussels in the beginning of 1843. She was engaged as teacher of English in a school for young ladies, completed her education in French, made considerable progress in German, and returned to Haworth at the end of 1843.

The novel entitled 'Jane Eyre, by Currer Bell,' published in 1847, was the first production of Miss Bronté's pen which caught public attention, but it was not her first venture in authorship. Her first essay was in a little volume of 'Poems by Currer, Ellis, and Acton Bell,' 1846, of which the poems passed almost unnoticed, but the success of the novel was immediate and extraordinary; and curiosity was for some time exercised not only as to its paterinity, but as to the identity of the three authors. Many people bearing manifestly the traces of a woman's mind, yet the general cast of thought, was urged on many sides, was as evidently unfeminine. The appearance almost simultaneously of other stories, marked by the same peculiarities of thought and general style, with the names of Acton Bell and Ellis Bell as their authors, served to stimulate still further the public curiosity, and when it was officially announced that Currer Bell was the daughter of a clergyman in a remote part of Yorkshire, and that the three sisters, Emily, Charlotte and Anne Bell were her sisters, there was a general feeling of surprise but, as alluding to incredulity. In truth, 'Jane Eyre' is a remarkable work, and as the production of the daughter of a country clergyman, it would be still more remarkable if it were necessary to suppose it accompanied with so wide acquaintance and so intimate knowledge of the human heart, and to portray diversities of character. 'Jane Eyre' was followed in 1849 by 'Shirley,' and that in 1853, by 'Villette,' both marked by the same vigour of intellect, and keen, in fact more marked, a consistent creation of characters. The motives, though with less of that somewhat wayward originality which had in her first work called forth so much adverse criticism, but at the same time had excited such intense sympathy.

What is unpleasant, painful, morbid in these powerful novels may, there can be little doubt, be set down to the action of disease upon an overwrought and intensely susceptible mind. Young as she was at her death, she was the last surviving of her brothers and sisters, and all her children. Emily Bronté (Ellis Bell), the author of 'Wuthering Heights,' next to Charlotte the most gifted of the sisters, died Dec. 19, 1848. Anne Bronté (Acton Bell), the author of 'Agnes Grey,' died May 28, 1849. Miss Bronté married in June, 1854, the Rev. Arthur Bell Nicholls, her father's curate; but pulmonary disease, the same insidious malady which had carried off her sisters, had already marked her as its victim. She died at the parsonage, Haworth, on the 31st of March, 1855, leaving her husband and two children.

The "Professor," a Tale by Currer Bell," a novel written in 1849, but laid aside and much of it recast to form 'Jane Eyre.' The "Tale of the Professor," 4to, 1857, has been published by Mrs. Gaskell.

BROSSÉA, a genus of plants, belonging to the natural order Eriocéace. The fruit of B. coquina, like that of Gaultheria procumbens and Arctostaphylos alpina, is succulent and greyish; it is a small, narrow, ovoid, berry-like fruit, about 1 millimetre in length, which is utilized in the manufacture of confitures. Several species of Gaultheria, with a similar fruit, are cultivated for the same purpose.

BROWN, CAPT. SIR SAMUEL, R.N., was born in London in 1776. At the age of eighteen he entered the navy, and served with distinction during the French war. He passed through the successive grades in his profession, rising to the rank of commander in 1811, and accepting that of retired captain in 1842.

It is however as a civil engineer that Sir Samuel Brown has claim to remembrance. To his ability and ingenuity may be traced the construction of the first iron suspension-bridges. The idea of substituting iron cables in the place of those made from hemp, first occurred to M. de Bougainville, whose account of a voyage which he made round the world was published in 1771. [Bougainvillius, J., Tableau du voyage de Bougainville, 1771.] He was, however, content to propose a suspension-bridge for a line of high mountains. A patent for this suspension-bridge was granted him, though a patent was taken out by a Mr. Slater, a surgeon in the British army, in 1808, little was done until Captain Brown carried out a series of experiments, the results of which were so satisfactory that the Board of Admiralty ordered him to carry out an iron suspension-bridge. Their use, it need hardly be added, has since become general. Iron suspension-bridges had, as is well known, been erected in several instances both in America and Europe before Captain Brown was the first to apply this construction to the wants of the British army, and it was generally regarded as insecure, except for crossing narrow streams, until Brown introduced his improved method of constructing chains for suspending the roadway. Instead of chains of the ordinary construction, he proposed to form them of long bars of flat or round iron, pinned together by short links and bolt-plugs. He made a model of his invention in 1813, having however designed and prepared specifications for suspension-bridges much earlier, but he did not obtain his patent till 1817. Brown's plan was soon adopted in Germany and other countries, and a patent proposed to use cables of merely the ordinary construction in the erection of his magnificent bridge over the Meuse Strait. The first extensive bridge erected wholly on Captain Brown's plan was the bridge which crosses the Tweed at Berwick, in which the length of the chord-line between the points of suspension is 409 feet: it was opened for use in July 1820. In 1821 Captain Brown commenced the construction of the Trinity suspension-pier at Newhaven near Edinburgh. He subsequently erected several other bridges and piers, but it may suffice to mention, as his greatest work, the suspension-pier at Brighton, which consists of four openings of 265 feet each, with a deflection of 18 feet. The Brighton pier has suffered considerable damage on two occasions, but has never been strengthened, and it has successfully withstood others of excessive force.

Captain Brown was knighted in 1835. He died on the 15th of March 1852.

BRUNEL, SIR JAMES, 11.

BRUNEL, SIR MARK ISAMBARD, was born on April 25, 1799, at Hacquerville, in the department of L'Est, a few miles from Bonen. His parents, who were respectable agriculturists, had four children, of whom he was the eldest. From his earliest boyhood he was occupied with mathematical and mechanical pursuits; and on being sent to the seminary of St. Niciaise at Bonen, preferred the study of exact science, mathematics, mechanics, and navigation, to the classics; and during his stay there, which was never longer than when buying himself in a joiner's workshop. He familiarised himself with the tools and some of their applications, and when but twelve years old was already proficient in turning and in the construction of models—ships, machines, bridges and other structures. This was little gratifying to his father, who would have preferred to see his son in the church or in the merchant's office.
BRU

89

BRY

On leaving the seminary at the age of fifteen, Bruel passed some time in the family of M. Carpentier, a friend of his father, at Rouen; and went through a regular course of lessons in drawing, perspective, arithmetic, and algebra, to so much interest in the astronomical part of his practical studies, that on his visits home he set himself to observe the stars, greatly to the astonishment of the villagers. He made an octant, guided by the one belonging to his tutor, and a telescope on a fixed tripod, and, having started a little factory, he studied the instrument, and constructed another of ebony, which enabled him to take trustworthy observa-

tions.

He commenced perhaps by M. Carpentier, who had been a trading captain, Bruel enlisted as a sailor in 1766, from which date up to 1783 he made several voyages to the West Indies. He was remarkable for his skill, intelligence, and good humour with which he discharged a seaman's duties; won good opinions for his honesty and temper, and his compan-

dies by using instruments of his own construction, and by making a pianoforte while the ship once lay at Guadaloupe.

During a visit to Paris after his last voyage in 1793, Bruel restored to raise his voice in one of the political clubs against the ferocious doctrines there actively pronounced, and thereby endangered his personal liberty; but, obtaining per-

mission from the minister of marine, he escaped to America, hoping to find employment for his abilities in a new country.

Bruel was appointed a fellow of the Royal Society in 1784. Bruel was always a liberal supporter of the party of his countrymen who were about to explore the wild and unsettled regions bordering on Lake Ontario, to survey the lands of a French company. The operations were carried on for two months, during which the party, seven persons in all, were driven for a considerable time by the weather, and gained great distinction.

In 1794 Bruel was appointed, conjointly with one of his fellow-

explorers, to survey for the canal which now connects Lake Champlain with the Hudson River. This was a very difficult task, in which his fertility of invention and readiness in overcoming difficulties were strikingly manifested, his career as an engineer may be said to have begun. When designs for the houses of congress were called for he sent in one of which, though the most simple and economical, was well received and magnificent for simple republicans. He afterwards acted professionally as an architect, and among other works built and fitted up one of the principal theatres of New York. It has since been burned down.

He was employed on the fort erected for the defence of the city, and in the establishment of an arsenal and foundry, where his ingenious contrivances for boring cannon and moving large masses of metal with facility, showed how successfully he could bring new ideas to bear.

In the family of his friend Carpentier, at Rouen, Bruel had become acquainted with Miss Sophia Kingdom. This acquaintance, and a desire to work among the scientific engineers of Europe, drew him to England. He married Sophia Kingdom, who, being at that time a lady of considerable fortune, produced an autographic machine, designed to copy drawings, maps, and written documents. Soon afterwards, he submitted to government a plan for making block-pulleys for ships by machinery, and was employed to carry it into execution in the dockyard at Portsmouth. The impugnity of this contrivance is not less remarkable than the accuracy and economy with which its operations are performed. It comprises, so to speak, sixteen different machines, all driven by the same steam-power; twelve of which cut as many logs of elm or ash into the shells of blocks of any required size, while nine fashion stems of lignum-vitis into poularies or saws, and form the iron pin, which being inserted, the block is complete. Four men with this machine turn out as many blocks as four-score did formerly, and at less cost. The supply has never failed, even in time of war, though 1600 blocks are required in the rigging of a single ship of the line. It results so satisfactory produced a corresponding liberality on the part of the government, and Bruel's respect, as he thought, beyond his expectation. The steam saw-mill in Chatham dockyard was erected by Bruel. The success of the circular saws there introduced led him to further improvements, by which in the cutting of veneers double the usual number could be obtained from a given thickness of wood. These seamless shoes for the army, which, after two years' trial, was given up from an economical motive. Among other inventions may be enumerated a machine for making wooden boxes; for nail-making; to twist, measure, and form sewing threads into bands; for rolling paper; a contrivance for cutting and shuffling cards without the aid of fingers, produced in reply to a playful request of Lady Spencer's; a hydraulic packing-press; new methods and combinations for suspen-

ding and for riveting iron and steel in wood; a method of fixing iron plates and flat anchors without centers. He was employed in the construction of the first Ramagate steamer, and was the first to suggest the advantages of steam-tugs for the Admiralty. He con-

structed a machine for using carbuncle acid gas as a motive power, and obtained a patent; also, for his son, several experi-

ments, for more than ten years, in the endeavour to bring it to perfection. Most of the mechanical difficulties were overcome; but although an intense power was obtained, and with a very low temperature, the economical advantages, as compared with the cost of the vapour of water, did not appear to be such as to compensate for the increased cost of the machinery, and the usual difficulties in its use.

Bruel's works of engineering construction are to be found in different parts of the United States. In 1810 he wrote a treatise on the subject which is most popularly known as the Thomas Tunnel. This great work, commenced in March, 1825, was successfully accomplished, notwithstanding the accidents, obstacles, and overwhelming difficulties that hindered its progress. The water broke in more than once, and flooded the whole of the excavations. Bruel, however, proved himself equal to each emergency, and his persevering genius at length triumphed.

The tunnel was opened to the public in March, 1843.

In 1796 Bruel was admitted a fellow of the Royal Society, in 1814, and was chosen on the council, and appointed vice-president in 1832-33. He was a member also of other scientific socie-

ties and institutions. The honor of knighthood was conferred on him in 1841. With advancing years he became more and more attached to his lady, with whom he resided at the same house during the whole of his life. Bruel was, however, one of the most confidential friends, and was enabled to know him personally, could appreciate his simple and noble character.

gineers; Quarterly Review.]

BRUSA. [BUSA.]

BRYDGES, SIR SAMUEL EGERTON, Bart., was born November 30, 1725, at Wootton Court, Kent. His father was Sir Edward B. Bart., one of the judges of the admiralty, and his mother was the daughter and co-heiress of the Rev. W. Egerton, LL.D., Prelate of Canterbury, &c. Young Brydges was educated first at Maidstone Grammar School, and afterwards at the King's School, Canterbury, whence he proceeded to Cam-

bridge, entered Trinity College, where he was made a fellow, and left the University without taking a degree; entered himself of the Middle Temple in 1753, and in 1757 was called to the bar. He never practised; however, but having married in 1760, devoted himself to literature, and especially to genea-

logical and bibliographical studies. His earliest appearance in print was as a poet, a volume of 'Sonnets and other Poems' being published by him in 1785. Soon after the death of the last Duke of Chandos, in 1790, his uncontrolled imagination, excited perhaps by his somewhat unfortunate genealogical inquiries, a large share of vanity, and a passion for titles, led him to stimulate his elder brother the Rev. E. T. Brydges, to prefer a claim to the barony of Chandos, alleging his descent from the first Brydges or Bridges, who bore that title. Litigation was protracted till June, 1796, when the House of Lords decided that the petitioner had not made out his right to the title. Henceforth every thing which Sir Egerton Brydges wrote, was more or less a wall for the last traces of the dignity, and he continued to describe himself ' per legem Terrae Baron Chandos.' The worth-

lessness of his claim is amply shown in a Review of the Chandos Peergage Case, adjudicated in 1803, and of the pre-

tension of Sir S. E. Brydges, Bart., to designate himself per legem Terrae Baron Chandos. 'The case, of course, was the same, and there was the same sort of evidence adduced, and the same sort of arguments urged in support of the claim. A fine point was raised as to the "Person" of the parties. One of the most impressive passages in all law books is F. Belis, Esq., Lancaster Herald,' 8vo, 1831. By improvident expenditure in the purchase and improvement of the estate of Denton, Kent, Mr. Brydges had early become involved in his pecuniary circumstances, and in 1810 he removed to Lea Priory, the seat of his son, where he expired himself by self-
BRONIN

[Chemistry, X. 1.]

BRYOZOA, a name proposed by Ehrenberg for those Zoophytes in which a higher organization is indicated by the presence of separate orifices for the mouth and anus. The same naturalist has applied the term Anthozoa to those Polyzoa in which the mouth and vent have but one orifice. The families of Zoophytes of these two great families have been observed by Mr. J. V. Thompson, and previously to the publication of Ehrenberg's name, his designation for this family, Polyzoa, is more generally received. Other names have been given to this interesting family of Zoophytes. Professor Owen calls them Molluscous Zoophytes, on account of the structure of the animal being supposed to ally them to the Mollusca. For the reason they have also been called Ascidiod Polyzoa (P. Aestivida). Milne-Edwards has also called them Tunicated Polyzoa (Polyzoa tunicae).

Mr. J. V. Thompson, in his Travaux, vol. 3, p. 1837, proposes to call them Oladochesme, in reference to the ciliated character of their tentacles. Mr. Brak in his Catalogue of the Zoophytes in the Collection of the British Museum, gives the designation of Polyzoa as prior to that of any others. [POLYZOA.

BUCHE, LEOPOLD VON, a distinguished geologist, was born on the 25th April, 1774, at Solpe, in the Ueckermar (Brandenburg). He came of an ancient and noble family, which reckons among its members not a few authors and statesmen. After the usual course of education, he became a student in the Prussian department of mines, and was marked for the earnestness of his scientific pursuits. In 1790 he entered the Mining Academy at Freiberg, where he had Hrnmboldt for a companion, and where Werner, his eminent founder, taught the then novel science of mineralogy, in a way so interesting and genial, as thoroughly to enlist the sympathy of his pupils. Under his teachings grew up a school of young philosophers, destined to widen and confirm his reputation, and amend his errors, among whom Von Buch was one of the most conspicuous. In 1792 the publication of his 'Mineralogisches Beschreibung der Carlsbad Saline,' formed the first of that series of valuable papers with which he enriched his fame, and for the rest of his life—always distinguished as much by conscientious inference, as by perfection of observation. Next appeared his 'Versuch einer mineralogenischen Beschreibung von Landek,' describing in part the island of Slesvo, followed shortly afterwards by 'Versuch einer geognostischen Beschreibung von Schlesien,' with (for that time) a very advanced geognostical map of the country. These works are written in accordance with the views of his great master, in which the Neptunian theory prevailed; and it is no small proof of the accuracy of the observed facts that they are now easy to be reconciled with the present more enlightened theory.

In 1800 Von Buch and Humboldt met in Styria, and spent some time in geological excursions among the Alps, and passed the winter together in Salzburg in observation and verification of natural phenomena. In the following year Von Buch travelled alone, on foot, to Italy, and far-roving pursuits led him into several different parts of the countries he traversed, in which, besides the clearness of perception, there began to appear doxas as to whether the Wernerian doctrine were tenable in its integrity. He grew misanthropic of his former views. Writing from Rome to his friend Mr. Buck, he 'Made a great tour through the provinces of ancient Campania, visited the ruins of several cities, and then go a few miles farther on, and you will find occasion, upon grounds just as certain, to maintain the very opposite of your former conclusions.'

In 1802 he returned to Naples, and betaking himself to the study of Vesuvius, described the phenomena in that picturesque and eloquent style which among other qualities characterised his writings. In 1802 he visited the volcanic region of Avverganna. He revisited Italy, and was present at the eruption of Vesuvius in 1802. The results of these five years of observation were published in two volumes 'Geogenetischen Beobachtungen auf Reisen durch Deutschland und Italien,' 1802, in which, though reluctant to throw into the light the Wernerian conclusions, he 'But for a short while was entirely carried, to the estimation of water, and declares basalt to be a rock of volcanic origin.'

For the next two years, from 1806 to 1808, Von Buch travelled into Scandinavia, and made some of his most interesting geological discoveries. He observed the manner in which the fact of the slow and continuous upheaval of the Swedish coast above the sea-level; and he made valuable observations in climatology and the geography of plants, as may be seen in his narrative 'Reise durch Norwegen und Lappen,' 1806-1809, of which a translation was published with notes by Professor Jameson in 1813.

The more interest attaches to these journeys as they were performed on foot. Few who met Von Buch walking with unsteady gait, among grassy heaths between the naked craggy crest coat with numerous pockets to contain maps, specimens, his hammer and note-book, would have believed that he beheld whom Humboldt describes as 'the greatest geologist of our age; the first to recognise the true connection of volcanic phenomena and their mutual interdependence in regard to their effects and relations in space.' Possessed of sufficient means, Von Buch could gratify his inclination for travel, and for the encounter of others, especially youthful students, less fortunate than that he had himself been.

In 1815 he sailed from England (accompanied by the Norwegian botanist Christian Smith, who afterwards met with an untimely death in Tuckey's expedition to the Congo), and on the 15th September visited the island of Slesvo, and appeared the first geological map of Germany in forty sheets, of which Von Buch, though anonymous, was the compiler and author. He had visited the Basaltic islets of the Hebrides and the Giant's Causeway on his return from the Canaries, and in 1823 he published 'Physikalische Beschreibung kanger der Canariischen Inseln,' with an atlas, of which the unanswerable works, 'Ueber den Zusammenhang der basaltischen Inseln und Ueber Erhebungen-Krater,' and 'Ueber die Natur der vulkanischen Erscheinungen auf den Canarischen Inseln in ihre Verbindung mit andern Vulkanen der Erdorberflache' may be regarded as supplementary. These volcanic researches alone would suffice to establish his reputation. The science of volcanoes—the fruitful source of many later advances—is therein developed and placed on a sure basis. He shows how the phenomena of upheavals are traceable to craters of elevation, and demonstrates the action of fire; and states his conviction that 'the ancient seas have not rolled away over the mountain chains, but that the mountain have been raised up into a new atmosphere by bursting through the series of strata in long lines—fissures—and that these upheavals have taken place at different geological epochs.

Von Buch's life is strikingly manifest by his labours. His papers in the 'Abhandlungen' of the Berlin Academy of Science, would alone form several large volumes. They exhibit the development of his scientific views from first to last. In 1806 he had suggested certain ideas in his paper 'Ueber das Fortschreiten der Bildungen in der Erde, hauptlich zur der progress of forms in nature, and when past the age of
fifty, he showed how the ideas had ripened in his mind by his papers on the *Ammonites, Cephalaspides, Fossilia, Praecambriana*, *Orbitisten*, *Pro-
dactyli,* and others, accomplishing for the geological branch of paleontology what Carter had accomplished for the physiological branch. In the words of the late Edward Forbes, he was Von Buch "who first developed the idea of the oblongomor-
phosis of genera, the great leading principle of natural history applied to geology," he pointed the way moreover to a new field of research. Von Buch's noble work shows to be deductible from the serevation of the leaves of fossil plants. And in his writings on climate, on haul, the temperature of springs, and the geography of plants—guiding principles apparent in all—he proves himself an able physician was Von Buch.

In his many journeys Von Buch visited Sweden and Norway, and Auvrigne a second time, and any excuse sufficed to draw him to Switzerland. He would leave his house in Berlin without telling any of his intention, remain away for weeks or months, and return as unexpectedly. He liked to find out and make the acquaintance of geologists of emi-
nence, and for this purpose he attended the meetings of naturalists on the continent and of the British Association in Eng-
l
land. He was present at the Werner Festival, celebrated with so much pomp at Freiberg, in 1856. He never married, was somewhat eccentric in his habits, but always serious as regards science. When asked for his titles he was accus-
ted to reply, "Royal Prussian Student of Mines." He was created a baron, a knight of the Order of Merit (Berlin), and of the Red Eagle, and held the appointment of royal chamberlain in the court of Prussia. He was a member of the Academy of Sciences of Berlin, and of the chief scientific societies of the near and far East. In 1826, he was elected a foreign member of the Royal Society of London, and in 1840 was chosen one of the eight foreign associates of the French Academy of Sciences. He died at Berlin, after a few days’ illness, on the 4th of March, 1855.

"Von Buch was a swapper," says F. Forbes, in his anni-
versary address to the Geological Society. "He went about casting the seeds of new researches and fresh ideas, wherever his prophetic spirit perceived a soil adapted for their germination. The world was his garden, and his super-

natural and natural history departments of his science. In all these he has been an originator and a discoverer. In every subdivision of all three he has been a seeker—a high merit in itself."

BUCOLITZIE, a mineral closely allied to Silimanite. According to Thompson it is composed of—

Polished of Manganese by (a specie) is.

It is found at Passa, in the Tyrol, and in several districts in the United States.

BUCIDA, a genus of plants belonging to the natural order

**Gymnosperms.** One of these species, *D. Bucida*, yields a bark which is used in medicine.

BUC. (Deer.)

BUCKINGHAM, JAMES SILK, was born in 1756, in the marine village of Flushing, near Falmouth, in Cornwall. His father was a sailor, and died while swimming. His mother sent him to school at Falmouth, and was desirous of bringing him up to the church, but he preferred going to sea, and made a few voyages to Lisbon, in the last of which the ship was captured and brought into a Spanish harbor by buccaneers. After some delay they were set at liberty, but on their way home were impressed for the British navy. Buck-

ingham however escaped the press-gang, returned to Cornwall, and entered into an engagement with a bookseller

at Devonport, in whose employ he remained about four years; and here he seems to have gained some knowledge of the trade of a printer. He however took to the sea again on board a king's ship, but deserted, returned home, and went to London, where, in 1789, he was apprenticed to a bookseller, and began to follow the trade. He afterwards was a bookseller in the Mediterranean trade, and made many friends at Malta and Smyrna. He then resolved to settle at Malta as a ship-owner and merchant, and having purchased a cargo of goods, sailed from London in April 1813. When the vessel reached Malta, the plague had broken out there, and no persons were allowed to land; the cargo however was taken on shore, and the ship then proceeded to Smyrna. While he remained at Smyrna, the many failures took place in Malta, and he among others lost all his property.

Buckingham then resolved to try his fortunes in Egypt, and left Smyrna for that purpose, August 30, 1813. He was well received at the British Embassy, and was introduced to the English ambassador, Sir John Conolly. He then met with the pasha, Mohammed Ali, who was then about on an expedition in Arabia. At this time there was much speculation about renewing the commerce with India through the Red Sea, and making a navigable canal from that sea to the Mediterranean. Buckingham had a desparch from Conolly, in which he offered his services to examine the Isthmus of Suez for an eligible track, and to trace as far as possible the course of the ancient canal. His offer, after some delay, was accepted, and he was sent out for the purpose. After several days as far as the cabarets, he started from Suez on the Nile; with the pasha attendant, for the purpose of travelling to Koseir on the Red Sea. His attendant deserted him on the route, he was robbed of everything he possessed, and was left entirely unaided. He was befriended by a poor Arab, and was able to make his way through the mountains, with some scanty covering, and at length reached Koseir, whence however he was obliged to return to Keneh, and thence to Cairo, without effecting anything. At Cairo he was introduced to the pasha, Mohammed Ali, with whom he had some long conversations, and having agreed upon the same terms as at Alexandria, as to the purchase of a vessel he had been able to purchase ships for him in India, and to encourage a trade between India and Egypt.

Mr. Buckingham then left Cairo for the purpose of pro-
ceeding to Bombay by the Red Sea, and reached Suez, October 16, 1814, and Bombay April 6, 1815, having been detained in Egypt. He found the merchants at Bombay distrustful of the pasha of Egypt, and unwilling to trade with him; he therefore accepted an engagement from the agent of the British Government at Muscat as commander of a ship of 1200 tons bur-
den, which was to trade with the East Indies. At Mus-cat, having agreed upon the same terms as before; he reached Suez, and traced the ancient canal as far as it had not been filled up and obliterated. After his return to Cairo the pasha had changed his mind as to the canal, but gave him a commission to purchase ships for him in India, and to encourage a trade between India and Egypt.

From this period his proceedings in the East are imperfectly known. In 1816 he was in Calcutta, and established a journal there, but the holdness of his censure of the mal-
administration of Indian affairs led to his expulsion from the

N 2
presidency of Bengal; his printing-presses were seized, and he was compelled to return to England. After a few weeks in London, Mr. Buckingham delivered many lectures against the monopoly of the East India Company, and in support of opening the trade to China. A liberal subscription was entered into to re-imburse him for the losses he had sustained by the suppression of his journal. He had been till then in the first rank among the contributors to the integrity and excellence of the Gentleman's Magazine, and had been the author of several periodical journals, and of 'The Athenaeum,' which is now the leading literary journal among those which are published weekly. In 1829 he published his 'Travels in Palestine'; in 1831 his 'Travels in Arabia; in 1832 his 'Travels in Tunisia;' in 1833 his 'Travels in Assyria and Media.' At a later period he made several tours through various parts of Europe and of North America. He published 2 vols. in Belgium, the Rhine, and Switzerland; and a fourth volume, which he published nearly three years in America, and traversed the United States in all directions, from Maine to Louisiana. His 'Travels' in America comprise,—3 vols. on the Northern States; 3 vols. on the Slave States; 3 vols. on the Eastern and Western States; and 1 vol. on Canada, Nova Scotia, and New Brunswick. Much of these volumes however consists of statistics, and a great variety of other matters of compilation. Their literary or other worth is very small.

In 1832 another Buckingham was elected member of parliament for Sheffield, and he retained his seat till 1835. He was a supporter of liberal policy, and especially of social reforms. For many years his chief occupation was the delivery of public lectures in various parts of the country. His character was one of high moral principle, and popular and pleasing, and his lectures were always fully attended. In 1843 he was the chief agent in establishing a literary club called the British and Foreign Institute, of which he was appointed secretary, but which ceased to exist in about three years. In 1840 he published 'Natural Evidences and Practical Remedies,' 1 vol., in which he expounded his views on many subjects connected with the public welfare. He was a zealous advocate of the temperance movement, and he was one of the signatories of the Temperance Declaration of 1851. In 1855 he published the first two volumes of his 'Autobiography,' and he intended to publish the next two volumes in the course of the same year, but he closed his life of extraordinary vicissitude and adventure on June 30, 1855.

The court of directors of the East India Company had made amends for their former ill-treatment by granting him a pension, which he enjoyed for a few of the last years of his life, and which is continued, we believe, to his widow, who is still living, having been his wife for fifty years. He was a fellow in the Royal Geographical Society, and was entered on the civil list. The manuscript journals of his various travels occupy, as he states in his 'Autobiography,' 28 folio volumes, closely written.

Buckland, THE VERY REV. WILLIAM, Dean of Westminster, an eminent geologist, was born at Axminster, Devon, in 1784. He was educated at St. Mary's College, Winchester, and from thence, in 1801, entered Corpus Christi College, Oxford, as scholar. In 1806 he was elected Fellow of this college. In 1815 he was appointed reader in mineralogy, and in 1818 reader in geology in Oxford University. His geological lectures were characterised by such clearness and comprehensiveness of description, and such apt illustration, that they met with brilliant success. Geology, as a science, was then in its infancy, and much of its subsequent vigorous advancement is due to Dr. Buckland's lectures.

The Geological Museum at Oxford owes its chief excellence to Dr. Buckland's industry in procuring and arranging specimens, particularly of the remains of the larger Fossil Mammals, and other animals from the caves in different parts of England and Germany. He spared neither pains nor expense in travelling to make the collection worthy of the university and the scientific world in general. He enriched it as exemplified in his 'Descriptive Notes,' with sections of 50 miles of the Irish coast, made jointly with the Rev. W. Conybeare, dean of Llandaff, during a tour in Ireland in 1813, and published the third volume of the 'Transactions of the Geological Society.'

In 1816 Dr. Buckland was elected a Fellow of the Royal Society. In 1820 he delivered a lecture before the university, which was afterwards published under the title 'Vindiciae Geologiae, or the Connexion of Geology with Religion explained.' The object of the lecture was to show that the study of geology has a tendency to confirm the evidences of natural religion, and that the facts developed by it are consistent with the best and purest traditions of the Creation and Deluge as recorded in the Mosaic writings.

In 1822 he communicated to the Royal Society an 'Account of an assemblage of Fossil Teeth and Bones of elephant, rhinoceros, hippopotamus, bear, tiger, hyena, and sixteen other animals of the Pleistocene epoch, discovered in a cave near Oxford.' Around the same period he published an account of a serpentine used to make the Copley medal, which in the same year the society awarded him the highest honour, the Copley medal. This paper was made the foundation of a treatise published in 1823 called 'Reliquiae Diluvii.' He was the author of the plan 'constituting the Action of an Universal Deluge,' which proved of essential service in the promotion of geological science.

In 1835 Dr. Buckland was made canon of Christ Church, Oxford. He was president of the British Association at his own instance, and on his bid, for the purpose of publishing his Bridgewater Treatise, 'Geology and Mineralogy considered with reference to Natural Theology,' 2 vols. 8vo. The discovery of new facts had materially advanced geological science, and in this work the previous diluvial theory, Dr. Buckland broke all the weight of his authority to support the views now generally received. One of the ablest of his numerous geological writings, as subsequently testified by Murchison and Sedgwick, was a sketch of the 'Elements of the geological sciences,' in which he showed, for the first time, that many crystalline rocks of this chain are of no higher antiquity than our Lias, Oolitic, and Cretaceous Formations.

The 'Transactions of the Geological Society' contain his 'Life of Dr. Buckland,' and his 'Lectures on the Geological Sciences.' Dr. Buckland's skill as a field geologist, as well as a paleontologist, and among them, his discovery of the south-western coal district of England (1825) may be mentioned as an example. It has stood the test of more than thirty years, and is still appealed to as a standard work.

Dr. Buckland was chosen on the council of the Royal Society in 1827, and in subsequent years up to 1849. He was one of the earliest fellows of the Geological Society, and he occupied the position of honorary secretary for some years.

His 'Lectures on the Geological Sciences' is a work that has been a monument of his science, and his 'Lectures on the History of the Earth' is a work of the same kind. His 'Lectures on the History of the Earth' was published in 1845, and contained a series of lectures on the history of the earth, which was delivered before the society in the years 1845 and 1846. The first volume of his 'Lectures on the History of the Earth' was published in 1845, and contained a series of lectures on the history of the earth, which was delivered before the society in the years 1845 and 1846.
bitter remarks made in the Chamber of Deputies by Dalong in reply to Bugeaud, in a debate on the conduct of Marshal Son and the Governor of Tangier that the government found it advisable on the occasion of Dalong's funeral to take precautions against an insurrection. A few months later Bugeaud's unpopularity was increased by the decisive measures he took for suppressing the various insurrections. He subdued Kabylie by destroying the inhabitant of the chief whose prowess and authority were really to be feared, to direct his whole strength against the disunited tribes, and reduce them successively to submission. Bugeaud returned to Paris to give an account of his mission. It soon appeared that Bugeaud knew better how to deal with the Arabs than the officers previously sent; and in 1840, affairs appearing very promising, Marshal Valles was recalled, and Bugeaud was appointed governor-general of the French possessions in Africa. An outline of his proceedings has been given under Algeria, S. I. It will be enough here to observe, that the maxims he was fond of repeating was that "to conquer the Arab you must first become an Arab," and that in accordance with this policy he organized the Zouaves and other irregular soldiers, characterized by their capacity for acting independently as well as in masses, their quickness of motion, and their daring, and who have since become so important a part of the French troops. In the forward establishments, a chain of fortified posts, he was enabled to maintain incessant attacks and surprises, never permitting any body of armed natives to collect without immediately dispersing them, and never allowing any hostile tribes to carry on any of their ordinary agricultural avocations. From his energy and ruthlessness, there was no escape for the uncivilized natives. Attacked in detail, resistance was useless; there was only the choice of submission or destruction. In three years Bugeaud was able to announce that there was no longer an enemy in the country. The Emperor of Morocco had ventured to oppose the progress of the French arms; but his coast-towns were ravaged, and at Isly, Bugeaud, with a far inferior force, had destroyed his army. For this last achievement Louis Philippe created Bugeaud Duke d'Isly; the Arabs gave him the more poetical title of Conqueror of Fortune. He returned to France in 1840; but in his absence Abd-el-Kader again collected an army, and, with the aid of the Timou and the latter's uncle, he went back, and with an iron hand quickly and effectively crushed the Arab rising. At the outbreak of the revolution of February 1848, Bugeaud was in Paris, and on the night of the 22nd the command of the troops was put into his hands. The government adopted energetic measures, but the king shrank from shedding blood, and the military command was placed in other hands. Bugeaud was not again employed till Louis Napoleon became president, when he was named to the command in chief of the army of the Alps. He was also elected by Charente-Inferieure representative in the National Assembly. But he enjoyed neither dignity long; he died of cholera, on the 10th of June, 1849. Bugeaud published memoirs on infantry manœuvres, on army organization, on the establishment of military colonies, and on a variety of matters connected with the government of Algeria.

BULGARIA, a country in Europe, is bounded N. by the Danube, which separates it from the principalities of Wallachia and Moldavia; E. by the province of Be-sarabia; S. by the crest of the Black Sea; and W. by the principalities of Servia, from which it is partially divided by the Timok, a feeder of the Danube. The area is about 23,000 square miles, and the population according to the census of 1844 was about 3,000,000, the majority of whom are adherents of the Greek Church. The Danube river flows along the province for not less than 400 miles, and is navigable for steamers and large vessels all the way. It forms numerous small islands in its course and a delta at its mouth; and on both sides of the river at intervals are extensive marshes, which in the dry season are very unhealthy and infested by mosquitoes.

The Balkan Mountains, the ancient Hyamus, rise on the southern frontier of Bulgaria, and extend down rapidly on the south side; on the north the slope is more gradual. The chain is traversed by many defiles and passes. From its crest numerous ramifications extend northward to the plain of the Danube. These branches are generally well wooded and covered with thick heaths, and they are separated by valleys or small plains drained by feeders of the Danube. The principal of these rivers, commencing on the Servian frontier and proceeding eastward, the Skadar, the Samara, and the Struma, tributary to the Danube, descend through the passes of the Balkans, and enter the Black Sea between Cape Eminush and the port of Varna. The snows that screen the valley of the Kamchi is on the north is the town and fortress of Shumla. The most important of the other tributaries of the Black Sea in Sisilia is the Para-wadi, which passes through the marshy lake of Devno and falls into the port of Varna. The Para-wadi River is identified by General Jochmus in his Notes of a Journey to the Balkan with the ancient Lyginc; and the site of Alexander's battle with the Triballii (a.d. 336) he considers to be the isthmus between the two lakes of Devno, a little west of the village Buyak-Aladin. Not far from the same spot, but nearer Varna, is the site of the great battle fought between the Sultan Murad and King Wladislaus in 1444. The site is usually identified by two large mounds called Sandashak Tepé and Marad Tepé.
The beautiful Emineh of Bulgaria. Kamentsch,1 colomn, is inhabited abundantly. Barley also of fine quality is extensively grown.

The eastern part of the pashalic of Nicopolis is well wooded as far as the neighbourhood of Kustench; it also possesses abundant pastureage, and, in ordinary years, when not visited by long droughts, it is very productive in corn. Wood for building purposes is abundant in the forests of Despoto-Dagh. Between Kustench and Sistova the plain of the Danube is occupied densely and solely by Bulgarians, and presents a fertile and pleasing aspect. Besides corn, the chief products are hemp, flax, sitar of roses, and tallow. Sistova is considered the capital of the Bulgarians; it is one of the most important towns on the right bank of the Danube, and carries on a considerable trade with Wallachia. Westward from Nicopolis, and throughout the greater part of the pashalic of Wallachia, the cultivation is for the most part confined to a few points, being met with only where there is water, and agricultural produce is raised merely sufficient for the local consumption. The plain of the Danube here partakes of the nature of a steppe, and cultivation prevails more in the mountainsous districts of the north than in the plains. It was long effectually checked in this part of Bulgaria by a restrictive system, by which the farmers could not sell their surplus produce without the pasha's permission, and at a price fixed by him. In 1837, however, by a law passed in Constantinople, these regulations have been very injurious to the trade of Widdin, which, however, has a considerable commerce in manufactured goods imported from Austria.

The tallow trade causes the rearing of large numbers of cattle in Bulgaria. Large herds of oxen, to the number of 40,000 or more, are fattened during the summer months, and slaughtered during the autumn, in the neighbourhood of Varna, Sistova, Kustench, and other towns, for their hides and fat; for beef is seldom eaten by the Moesians, whose favourite animal food is mutton and goat. There is a depot at Varna for the tallow and other products of the province. Owing to the difficulties, tediousness, and expense of clearing the spruce forests, the corn-growing countries are short of timber. The jealous regulations, the corn and other products of Bulgaria are generally brought by land carriage to Varna for export even from the plain of the Danube. Corn, however, for export to Constanti
tenople, is generally conveyed in small vessels, of from 30 to 100 tons, which are very numerous on the river, to Matzin, a small port opposite Braiboff, and thence embarked in larger vessels. From the roadstead of Kustench also large quantifies of corn are occasionally exported; but the exposed condition of this port since the destruction of its mole (built by Constantine the Great) is a great obstacle to its trade. Its position, however, has been at all times considered of great importance, as it is only 30 miles distant from Gornaow on the Danube. A canal was projected in 1857 to unite the two points, and to give a short and direct route to the Danube trade, by avoiding the great northern bend of that river, and the intricate shoals and mud-banks in its month. This project has been recently revived, and will probably be one day executed.

Besides horned cattle, including buffaloes, Bulgaria rears a great many horses of inferior breed, sheep and goats in great numbers, and swine for the consumption of the Christian part of the population: pork to the Moesian, as to the Jew an abomination. The characteristics of the products are all of a coarse description, and for home consumption. The imports are manufactured goods, coffee, spices, sugar, salt, &c.

The principal towns of Bulgaria are—Widdin, Nicopolis, Sistova, Kustench, Silistria, Russovo, Tarnovo, Sophia, Varna, Kustench, Shumla, Nissa, &c., of which the most important are described under their respective names.

Bulgaria comprises the greater part of ancient Muscovia, which was possessed in the time of Darius by the Getae, and in the time of Alexander by the Triball. It is a very i-
wresting country for its historical associations, to illustrate which there is great need of enlightened exploration. General Camouflet, in the already quoted, has thrown great light upon the early history of the town and the campaigns of Alexander in this country. He supposes Damas to have crossed the Balkan by the pass to the north-west of Mesembria, and to have marched northward to Isatacha by the same route. It was Sir James规划, supporter of the Corn Laws, advocated triennial parliaments, was agan

st property qualification for members of the House of Commons, maintained the necessity of national education, and was a strong advocate of the Roman Empire. He early distinguished himself by his speeches on colonisation, and by the ability with which he advocated improved principles and practice in colonial government. When the Earl of Durham was sent out in 1856 as governor-general of Canada, he advised Mr. Bulwer that he had contributed largely to the Report which was presented to parliament by the Earl of Durham, and published in 1859. After his return from Canada, Mr. Bulwer commenced the practice of the law, in appeals from the colonies and from Hindostan to the Privy Council. In 1841 Lord Melbourne appointed him secretary of the Board of Control; and Lord John Russell, after he became premier in 1846, made him Judge-Advocate General, with an understanding, as is said (which he was not realised), that he was to take in some way as colonial minister, though not included in the department. In November 1846 he was appointed a queen's counsellor, and in July 1847 was sworn of the Privy Council. Upon the re

turn of Lord Melbourne in 1848, Mr. Bulwer was made as head of the board, he was appointed to that office in Nov. 1847. He died in London, Nov. 26, 1848.

Mr. Bulwer was a ready extemporaneous speaker, but was accustomed to be excused for only making up his speeches in their whole extent. He also wrote for the periodical press, especially the 'Morning Chronicle' and 'The Globe,' and for the 'Edinburgh Review' and 'Westminster Review.' He also wrote for the 'Colonial Magazine' a series of papers on 'Responsible Government for Colonies,' afterwards published as a small volume.

Bumella, a genus of plants belonging to the natural order Sapotoceae. Many of the species are used in medi

cine. B. myra has a bitter and astringent bark, which is used in China for the treatment of fever and cholera, and is sold in Europe under the name of 'chinsa.' The fruit of B. cycosidis is astringent, with some of a bilious nature, but is of a mild and milky fruit. The fruit of B. cycosidis is astringent, with some sweetness, and is said to be useful in diarrhoea. The flowers of B. gracilecula have a heavy unpleasant odour. (Linley, Vegetable Kingdom.)

Burton, Miss. [D'ARBLAY, Madame, S.1.]

Burns Island, Fileyshire, Scotland, a town, royal burgh, and sea-port, in the parish of Burntisland, on the north or left side of the Firth of Forth, is situated in 56° 4' N. lat., 3° 13' W., long, about 5 miles nearly due north from Leith. The population of the royal burgh in 1851 was 2329, of the parochial burgh 2724. The burgh is governed by a burgh council, of whom one is provost; and united with Kirkaldy, Dysart, and Kinghorn, in returning one member to the Imperial Parliament. Burntisland was made a royal burgh in 1568. At the General Assembly which met here in 1601 James VI. took the oath to the Covenant. The town was fortified in the reign of Charles I., and besieged and taken by Cromwell, who repaired and considerably improved the harbour. The town chiefly consists of two parallel streets terminated by the harbour on the east. The harbour is deep and well sheltered. Between the two streets is an area of about 65 acres, which was partly filled up in the latter end of the 17th century. In the year 1676 a new road was opened from the town to the sea. The harbour is about 540 yards long by 150 wide. The town of Burntisland is for the most part built of stone, and is very neatly built. There is a good dry dock; and on the western pier is a lighthouse, the light of which may be seen a distance of seven miles. Burntisland formerly possessed a considerable trade. About 1656 there were twelve ports, including St. Andrews and the new extensive
port of Kirkaldy, which were subordinate to Bertrieland.

For many years past its traffic has been confined to that arising from the curing of herrings and from distilleries in the neighbourhood. Ship-building is carried on. There is daily steam communication with Granton on the opposite coast, and the Edinburgh and Northern railway opens up a direct communication with the whole north-east of Scotland, the passage across the Firth being effected here by a floating railroad.

The parish church was built in 1832. There are also a Free church, and chapels for Episcopalians and United Presbyterians.

North from the town, on the summit of Dunearn Hill, an eminence rising 696 feet above the sea, is a level space surrounded with a number of loose stones, which has been called Agricola’s Camp, and supposed, very improbably, to mark the site of a Roman encampment. On another eminence overhanging the harbour stands Rossend Castle, erected about the 18th century.

BUTE, one of the islands which compose the county of Bute, Scotland, is situated in the Firth of Clyde, between 55° 46' and 55° 50' N. lat., 4° 56' and 6° 10' W. long., distant about six miles from the opposite mainland of Ayrshire, and about half a mile from Argyleshire, from which county it is separated by a narrow and crooked but picturesque channel called the Kailes of Bute. The population of the island in 1851 was 10,681. The island is about 16 miles long, and varies from three miles to four miles in breadth. To the north it is elevated, rocky, and baren; the central part is diversified by bays, valleys, and fertile tracts; and the south end is hilly and divid’d from the rest of the island by a low and sandy plain called Langel-chord. The coast is rocky and indented by bays. The soil of the island consists of clay, loam, and sand, with moss lying on gravel. The greater part of the arable land is inclosed and cultivated, barley, oats, potatoes, turnips, and the artificial grasses are all cultivated with success. About the middle of the island are three small lakes—Loch Fad, Loch Aesog, and Loch Qtin. The climate though damp, is mild and temperate, and the island is much resorted to by invalids, Rothsay being one of the favourite watering-places of the Clyde. The minerals are limestone, freestone, slate, and some indifferently coal. Beds of coral and shells, of considerable thickness, are found in several places half a mile from the sea-coast.

Bute island contains many remains of antiquity. Dungie, or Dunagollan, a vitrified fort, attributed to the Danes or Norwegians, and situated on a lofty crag, is the south-west part of the island, is an object of interest and curiosity. In the southern extremity of the island are the ruins of an ancient chapel. Not far from the ruins are the remains of a circular erection about 30 feet in diameter and 10 feet high, known as the Devil’s Cauldron; the object for which it was erected has not been ascertained. Bute, and the adjacent islands, were long subject to the Norwegians. Haro of Norway in 1263 took possession of Bute, but after his defeat it returned to the allegiance of the King of Scotland.

Edward of England held it till 1312, when it fell into the possession of Bruce. Robert III. and James III. made the island their occasional residence. It was garrisoned by Cromwell, and was the scene of the Earl of Argyle’s unfortunate landing in 1665.

(NEw Statistical Account of Scotland.)

The Bute, a genus of Birds belonging to the order Raptura and the family Falconidae. It includes, according to Yarrell, two British species, B. vulgaris, the Common Buzzard, and B. lapponus, the Rough-Legged Buzzard. [FALCONIDAe] Various other species of the Falconidae have been included under this generic name. (Yarrell, British Birds.)

BUTYRONE. [Chemistry. S. 2.]

BUTYRYLE. [Chemistry. S. 2.]

BYRSONIMA, a genus of plants belonging to the natural order Malpighiaceae. The bark of the species is astringent, and is used extensively for tanning the hide. The wood of some of the species, especially B. berberisfolia, is of a bright red. The bark of B. cassiafolia is used in fevers. B. cassiafolia is one of the thousand remedies for rattlesnake bites. It is called Chapera Mancha. The Almococo Bark is the produce of B. lasiosepala, B. hophaliafolia, and B. coccoloba folia. The acid and astringent berries of B. speciosa are said to be good in dysentery. (Lindley, Vegetable Kingdom.)

BYTOWN, Canada West, the chief town of Carleton County, is situated in a very beautiful part of the country on the Ottawa, near the junction of the Rideau Canal with that river, in 45° 29' N. lat., 76° 15' W. long.; distant 128 miles N.E. from Kingston, and 284 miles N.E. by E. from Toronto: the population of the town in 1851 was 7720. The lower town, which is the older part, is that in which business is generally carried on: the upper town is of more recent erection; it is situated about half a mile distant on a more elevated site, and consists chiefly of private residences. Considerable improvement has taken place in the appearance of Bytown of late years. Several handsome stone buildings have been erected. The town contains places of worship for Episcopalians, Presbyterians, Wesleyan Methodists, Baptists, and Roman Catholics; several schools, a commercial reading-room, a mercantile library association, a court-house, barracks, and a jail. Bytown is supported chiefly by the lumber trade, a term applied to the system of floating large rafts of rough timber down the rivers of America to the depots and ports in the lower parts of their course. Timber cut on crown-lands and brought down the Ottawa River is measured at Bytown, and the owner gives bond to pay the duties at Quebec. The value of timber brought down the river in one year, 1844, was estimated at 341,750$. About three-fifths of the whole being cut on crown-lands was liable to duty, amounting to about 24,000$. Pairs are held at Bytown in April and September. Steamers ply between Bytown and Grenville on the Ottawa, and between Bytown and Kingston on the Rideau Canal.
CA-belot. [Whal.,
CACO.DY. [CHEMISTRY, S. 1.]
CADDICE, CADDIS-WORM, or CAD-BAIT, the com-
non name for the larvae of the species _Ptygomea_, which
reside in the water, in cases which the form of various sub-
stances, such as _live_ of stick, grains of sand, small stones,
&c., which are held together by a silken thread secreted
in their bodies in the same manner as in the silk-worm.
The case acts as a protection to the larva, and it is capable of
drying out its head or putting it out, according to circum-
cstances.

CALAMOPHILUS, a genus of Birds belonging to the
family _Paridae_ and the tribe _Incanceses_, sub-tribe _Dentroastes.
C. biarmicus_ of Yarrell is the _Porus biarmicus_ of Pennant
and other writers. This bird is common in Great Britain,
and is known by the name of the Bearded Tit. (Ttywinsk.)
(Tatelwill. _British Birds._
CALEDONIAN CANAL, a connected series of lakes and
canal extending through Glenmore, or the 'Great Glen of
Alien', a-straight line from the Western Ocean with the North
sea, a distance of 40 miles. Various canal companies were
formed for the purposes of extending the above line of
work, which afterwards failed, and the company was
founded by a charter granted in 1790, with capital of £1,000,000.
The canal commenced in 1803, and was completed in 1823.
Telford's work was of a uniform width, 26 feet 4 inches
wide, and 8 feet 6 inches deep. The canal was designed
for a lock-replica at the open end, and for four locks
altogether at the lock-gate end. The lock-gate lock was
80 feet long, and the lock in the middle of the canal
120 feet long. The canal was opened on the 11th of March
1823.
CAPE DIAMOND. On the coast of Madagascar, five
miles N.W. of the peninsula of Cape St. Marie, an island
is supposed to be the source of the diamond. The
island is inhabited by a savage tribe of negroes, who are
assuredly the owners of the diamonds. The island
is about 16 miles long and 12 miles wide. It is
supposed that the diamonds are melted down at
various places along the coast, and that they are
collectively called 'Cape Diamond.'
CAPE YORK. The name given to the western
extremity of the island of New Holland.
CAPTAIN. A Caledonian Canal commences on the south-
west end of the shore of Loch Eil near Fort William, in
56° 00'. N. lat., and 5° 12'. W. long., and joins Loch Lomond by
cutting a mile in length; a short cutting of about 2 miles
through Loch Lomond, with Loch Oich; a canal nearly 6 miles
long, from the north-east end of Loch Ness; and a canal of about
7 miles in length continues the passage to Criancharn near Inverness;
whence by another short artificial cutting, it goes into the Moray Firth on the shore of Lochs Heavenly,
in 57° 45'. N. lat., 4° 15'. W. long. The length of this
communication divided by the west and east seas is in all about
60 miles, of which rather more than 37 miles are through
natural lochs or lakes, and about 23 miles through artificial
cuttings. The summit level at Loch Oich, which is about
94 feet above high water on the east coast at spring tide,
there are 36 lochs, in the 14, 16, to the west of Loch Och, and 14 to the east. The locks are about 170 feet in
length and 40 feet in width, the rise of each lock being 8 feet.
The width of the canal at water surface is 120 feet; at the
bottom 50 feet; the depth of water is 17 feet. There were
considerable difficulties to be overcome in the
construction of the canal. The object propounded in this
rational work was the avoidance of the tedious and often
dangerous voyage of the Orkneys and Cape Wrath. From
Kintraid's Head on the east coast to the Sound of Mull on the
west coast the passage by the Orkneys and Cape Wrath is
about 600 miles, while by the inland navigation the
distance is only 254 miles. By the Cape Wrath passage
many shipwrecks had occurred. A large amount of public
money has been expended on the works. The returns have
been very small in comparison with the cost; one chief
cause of the failure was the indolent conduct of the
agents of the legislature in imposing duties on the importation of timber
from the Baltic, in order to encourage the employment in this
country of timber of Canadian growth. For a number of
years after the opening of the canal vessels were
considered as the means of moving transportation and contrary winds; since
1847 this has been remedied by the establishment of steami-
vessels, causing a considerable increase in the number of
}.
 republicain, he was yet eminently conservative in spirit, a staunch defender of all southern rights, and the inflexible supporter of the 'institution' of slavery. In general and international politics, he commonly took the popular, or, as it is usually termed, the patriotic side. He died March 31, 1850. Many of Mr. Calhoun's speeches were printed as separate publications about the time of their delivery; and his collected 'Works' are now in course of publication at Charleston and Columbia.

Of the small number of birds belonging to the order Grallatcric and the family Charadriidea. It has the following characters:—Beak as long as the head, straight, slender, flexible, compressed at the base, with the point dilated and smooth; nostrils basal, lateral, narrow, long-twigged; primary feathers short, forming a smooth point of the beak; wings of moderate length, pointed, the first quill-feather the longest; legs of medium length, naked above the tarsal joint; feet with three toes, all directed forwards, with a very small connecting membrane at their base. Gould, in his 'Birds of Europe,' regards the knot (Tringa canutus) as a species of Calidris. With this exception, the only British bird which is a species of this genus is C. arenaria, the Sandpiper. It is an inhabitant of most of the shores of Great Britain and Ireland. It obtains its food by probing the moist sands of the sea-shores, from which it obtains minute molluscous, shrimps, annelids, &c. It visits the shores of Sweden, and is stated to breed still farther north. John Richardson says it breeds on the coasts of Hudson's Bay, but it does not appear to breed in the British Islands. (Yarel, Brit. Birds.)

CALIFORNIA, STATE OF, one of the United States of North America, is bounded N. by the United States territory of Utah, S. by the State of Texas, and E. by the Mexican territory of Lower California. Its western boundary is the Pacific Ocean, along which it extends from 32° to 49° N. lat., its eastern boundary is defined by a line which runs along 120° W. long. from 42° to 55° N. lat., thence in a south-westerly direction which intersects the Rio Colorado in 35° N. lat., whence it is continued down the mid-channel of that river to its mouth in the Gulf of California, 33° N. lat. The area is 180,000 square miles, or 187,263,600 acres. It contains 507,067. The tract of country which now forms the State of California was, until lately, the coast section of the territory of Upper (Alta) or New (Nueva) California, the north-western part of the Mexican republic. It was ceded to the United States of North America by treaty in February 1848, and has since been admitted into the Union as a sovereign state. The extraordinary increase of its population will be seen by the following statement:—In 1862, Humboldt, a monk, who had applied at the head of the missions, estimated the whole population of California, which included, besides the present State of California, the territory of Utah and (in part) that of New Mexico, at 18,682, of whom 15,652 were 'converted Indians.' The official statement of the resident in California in 1829 was 20,105, of whom 18,783 were converted Indians. After the suppression of the missions the Indians became more scattered, and no official statement of the population was made. The first federal census after the cession of California to the United States was in 1850, when the State of California had a total population of 117,583. In 1862 a census was taken by the State authorities, when the agents' report gave the population as 264,435; but the Secretary of the Interior of the United States, in his report to Congress, states that these agents declare their inability to obtain the numbers of 'the whole population of their respective counties,' and he thinks it necessary, in order to render an approximately correct statement, to add one-sixth to the number returned. He therefore gives 306,607 as the population in 1850, of whom 210,858 were whites, little more than 30,000 being females, and 105,344 being citizens over 21 years of age; 4200 were negroes, of whom the females were under 300; 573 were Indians; 270 were domestic servants; and 250 foreign residents, of whom about 25,000 were Chinese. California sent in 1857 two members to the Congress of the United States, and like each of the other states two members to the Senate.

Coast-line, Surface, Hydrography.—The State of California owes its characteristic features to two great ranges of mountains, the Sierra Nevada and the Coast Range, which traverse it from north-west to south-east, having between them the splendid valley of the Sacramento and the Jozquin; on the eastern side wide sandy plains, and on the west a narrow slip of coast. The coast of California is generally rugged and precipices. Beginning at its southern extremity, it makes a bold semi-circular sweep to the north-west as far as Point Conception. Of this part of the coast there are several small islands and rocks, and the coast-line is indented by several bays and harbours. The only valuable one of these is San Diego Bay (33° 41' N. lat.), which has an excellent natural breakwater at its mouth, formed by a narrow strip of sand which extends from the projecting lands, is wide and spacious, and forms an excellent, though at present little-used, harbour. The harbours of San Pedro and Santa Barbara are also available for craft of considerable burden. From Conception Point to Point Arena, the northernmost point of the southern extremity of Monterey Bay, one of the safest and most capacious harbours on this coast; it is said to be capable of containing at one time the navies of the world. From Monterey Bay the coast continues as before for about 70 miles, in a direct line to the almost untravalled bay of San Francisco. The entrance, which is nearly in the centre of San Francisco Bay, is only about a mile wide, but the bay itself opens out for more than 80 miles both on the right and left; its entire length is 70 miles, with an average breadth of 8 miles, and it has a coast of 276 miles. By projecting points of land, several small inner bays are formed, the principal being San Pablo and Suisun bays. It is land-locked on every side, and quite safe within, but a bar at the mouth renders it dangerous for large vessels. The natural outlet of the valleys of Sacramento and Jozquin, with their wondrous mineral riches and vast agricultural capabilities. Beyond San Francisco Bay is Port Bodega, where was formerly a Russian station. A little further north, the roads divide, but less broken than before, to Point Delgado, beyond which is the bold headland of Cape Mendocino, 40° 21' N. lat., which forms the southern point of the bay of Trinidad, in which the coast of California terminates. The mountain masses of Lower California extend undivided into the State of California as far north as the snow-capped peak of St. Bernardino, 34° N. lat., where they divide into the two great ranges already mentioned. From St. Bernardino, the mountain ranges are generally parallel direction. The eastern range, called the Sierra Nevada, or Snowy Range, is by far the loftiest, of its peaks being above the line of perpetual snow: the Saddle Peak is 7500 feet high, the Table Mountain 8000 feet, the Butte 9000 feet, and Mount Shasta at the northern extremity of the range (41° 34' N. lat.) 14,500 feet above the sea. This range is traversed by few and those very elevated passes. North of 39° N. lat. its slopes, especially on the western side, have vast forests of pines and firs. The Sierra Nevada from the coast averages about 200 miles. The Coast Range runs at a short distance only from the coast, to which it is generally nearly parallel. Its usual height varies from 3000 to 5000 feet, and it extends as far south as the head of San Francisco Bay, is 9700 feet above the sea. This range is broken near Monte Diavolo by the united Sacramento and Jozquin rivers; decreases in altitude towards the north; and finally re-unites with the Sierra Nevada near Mount Shasta. From this point northward the surface of the country is wholly mountainous and little known; the Sierra Nevada with its offsets and connected ranges occupying the entire breadth of northern California, and extending north-westwards at last to the coast of Oregon. The Sierra Nevada, being the highest of the mountains of the Sierra Nevada and the great valley is a line of lower mountains; and from both the Sierra Nevada and the Coast Range lesser lateral ranges and offsets diverge throughout California, forming numerous narrow valleys and ravines.

The basin included between the two main ranges, though only one geographical formation, bears the name of the Sacramento and Jozquin valleys, from the rivers which rise in them, and empty into the Pacific Ocean. The upper part of the rivers is very turbulent, and they empty into San Francisco Bay. This fine valley is upwards of 500 miles long and 40 miles wide. It has evidently at some remote period been the bed of a vast lake of which the Sierra Nevada and Coast Range are the residual cabins. The southerly direction which it has probably been drained by some convulsion of nature having broken a passage through the Coast Range at San Francisco Bay. At the southern extremity of the valley are the Tulare (Borivali) Lakes, which during the wet season extend above 100 miles.
CAL in length, but in the dry season have little water, and are fordable in many places. Within the last year or two a commencement has been made towards embanking these channels by means of faggots of flag-hillocks. Dugouts to the annual floods. The soil and climate of this great valley vary considerably, but a large part of it is very fertile, including most of the eastern side, which is intersected by numerous streams. Along which the land is extremely rich and fertile. The coast is of fine profile, with the gambling deserts, used, being broken into rugged hills at its northern end, and in many places along its eastern side by well-wooded spurs from the Sierra Nevada. Towards its southern end by the Tulare Lakes, and along the banks of the two great rivers, it is dotted with beautiful backwater tracts and oxbows, formed in undulating slopes, which break into low hills as they approach the bases of the mountains. The richest and most picturesque part of this fine valley is that central portion of it which incloses San Francisco Bay and the delta of the Sacramento.

The coast district west of the Coast Range—almost the only part of California inhabited previous to the American occupation, but now by us means the most populous part of the country—is of narrow coastal valleys, the seats in former days of the mission stations, around which the industry of their occupants had caused most of the cereals and fruits of temperate climes to flourish abundantly. Along a good part of the coast the mountains come close down to the sea; but above and inland, the country rises gradually, and even very high, yet retaining mainly to the superior attractiveness of the mountains and great valleys, and partly to its being occupied by hostile tribes of Indians. It is believed that while much of it is of comparatively small account, there are very extensive regions of fine and hitherto unappreciated land. The country along the Colorado is supposed to have a rich alluvial soil; but near its entrance into the California Gulf the country about it is dry and barren, and the climate extremely hot.

The most important rivers of California are the Sacramento and the San Joaquin: the value of the Colorado remains to be fully ascertained. The Sacramento rises at the northern extremity of the valley of the same name; its head-streams issuing chiefly from Mount Shasta or Kame of its spurs. Its course throughout is a broad and level, and it receives on its left bank a great number of affluents from the Sierra Nevada. Most of these are mere mountain torrents; but several of them, as the Feather, the American, Cosumnes, and the San Joaquin, have been converted into fine and fertile districts. The Sacramento receives the San Joaquin, and the United river turns abruptly to the west, and soon after expanding to a considerable width opens into San Francisco Bay. The entire length of the Sacramento is about 900 miles; its width at the San Joaquin junction is 10 miles; at its middle distance from 290 to 300 yards, and it is navigable at all seasons up to Sacramento city, 150 miles from its mouth. The Sacramento is subject to great floods during the wet season, and on the melting of the snow on the Sierra Nevada. The San Joaquin issues from the Tulare Lakes at the southern end of the great valley. Its course is north and north-east, and like the Sacramento it receives numerous tributaries from the Sierra Nevada. During the wet season the San Joaquin is greatly augmented in its course, and since 1850 has overflowed its borders. It is navigable for vessels drawing 3 feet of water up to Stockton, 3 miles above its junction with the Sacramento, and for vessels under 15 tons up to the Tulare river. The San Joaquin abounds in fine fish, and the taking and curing of salmon afford employment to many persons. The banks of the river and its tributaries are generally extremely fertile, and agriculture is pursued with much diligence. The country watered by the San Joaquin and its affluents is becoming rapidly inhabited, and the value of its land, even in the districts which drain the south-eastern portion of California, and which falls into the Gulf of California, belongs rather to New Mexico, under which it is noticed. Except during the wet season, this river, though draining a vast extent of country, is very sluggish, and few boats can pass for 15 miles without being drawn. The total quantity shipped in 1853 from San Francisco during 1852 was 46,526,574 barrels; but this does not show the entire amount exported, as large quantities are taken abroad in small vessels without being entered. If 10 millions of barrels had been added to this the total quantity shipped in 1853 from San Francisco would be about 65 millions of dollars. The quantity received at the mint of the United States in 1852 was 136,747,935 dollars. Since that date an Act of Congress has been passed for establishing a mint in California. The total shipments of gold from San Francisco from April 11, 1849, to Dec. 31, 1856, inclusive, were valued at 322,399,836 dollars.

What is known as the Gold Region of California extends for some 500 miles in length, with a breadth of from 40 to 50 miles, following the range of the Sierra Nevada. It occupies the lower mountains of that range lying between the
central mountains and the valley of the Sacramento and the
San Joaquin. These mountains range from 4,000 to 6,000
feet above the sea and give rise to the numerous
gulleys and ravins, or in the sandy beds of the mountain
streams on their way towards the two great rivers.
The geological formation of this region is very similar to
that of the gold mountains of Australia and the Ural Mountains of
Russia. (A. L.) Whether this gold has been found in situ it has been
in connection with quartz; and the water-worn gold found in the
dehis of the rocks and the sands of the rivers in like manner shows, by its
frequently being enclosed to small particles of quartz, that it was
once in the sands of the rivers. The main region, as we
have said, is the low-r mountains on the west side of the
Sierra Nevada, but gold has been also found in the lofty
central heights of the Sierra Nevada, and on its eastern side. It is
reported that gold has been found in the Coast Range, especially in the
narrow valleys on its western side, and also in the connected ranges.
Indeed Drake's words seem now singularly applicable; for there appears
to be hardly any "part of this country where there is not special
likelihood of gold."

Nor is gold the only important metal which abounds,
though it is the only one to which much attention is at present
given. A mine of quicksilver has long been worked in the
region of San Francisco Bay, and grows frequently to a depth of 240 feet
below the surface and is easily procured. But the metal is believed also to be widely spread
and in valuable veins in other parts of the state. Silver ore of
great richness has been found at Monterey and elsewhere. Copious
springs of the mineral in the mountains are also believed to abound.
Coal is profitably worked at San Francisco, and is supposed to exist in extensive beds in other parts.

Botany and Zoology—The botany of California is of a
peculiar and interesting character. It contains among other
striking plants some noble pines, especially one called from
its discoverer, the Douglas pine (Pinus Douglasii), which occurs on the mountains about San Francisco Bay, and grows frequently to the height of 240 feet
above the sea. It is usually found at an elevation of 60 feet.
This tree is the oak of the Indians. The P. Sabinius, P. Lambertina, and P.
Nobla are of less magnificent but still very large dimensions,
and great beauty. The live oak (Quercus virginia) grows to a
considerable size on the lower hills of the west side of the
Sierra Nevada, and on it Fremont found annually large quantities of
mistletoe. The white oak is common in the valleys. The
maple, ash, beech, and chestnut are the other more usual
dean woods of the forest. There are forests which greatly extend south of 39° N. lat. Two or three kinds of
Arbutus abound on the hanks of the rivers and the margins of the
forests. The Scilla exelsa grows everywhere along the
coast; its root is the squash of the Indians, with which they make tables of foreign kinds. The
Helonias tenax are made by the natives into a very tough
cord for snaring deer, &c.; and the olives and sassafras are used by them for coap. Large numbers of Pokemoniaceae,
especially some beautiful specimens of the Lepisophora
and Glis; some curious plants belonging to the genera Nema-
phila and Emmenentha; several new genera of poppies,
Bachettia, lupines, Calochortus, Cyclobothrs, Callicipra,
Brodonia, &c., stamp the vegetation with a character quite
unlike that of any other part of America.

The black bear, theizzly bear, and the barren-ground
bear, the raccoon, American badger, gopher, ermine, wessel,
mink, martins, and skunk are common in many parts; as are also
the beaver and the musk-rat about the mouth of the
Sacramento; all of these are much sought after for their
skins. Several kinds of wolves, foxes, and lynxes abound in the
dense forests of the north, where they prey on the
umerous deer and other animals which frequent those
regions. Of the birds, that which is the most important, and the
tall-tailed or jumping deer, the elk, and the great antelope (A. jucifer)
are the most plentiful. Mountain sheep abound. The bison is only occasionally met with.

Among birds the first place is due to the great Californian
duck. This species is found in California in abundance
only to the South American condor in size, and very similar
to it in its h habits. The black vulture, the turkey buzzard,
the golden eagle, the badger, the p-reigning falcon, the
jaguar, the coy, and several other hawks and connected
species as well as owls, are more or less common. Most of
the ordinary European singing birds, swallows, woodpeckers,
&c., or birds to which similar names have been given,
are also abundant. The humming-bird is common in the south. Grasshoppers and the fire-fly are in abundance in
this kind—than have been found in any other country. The bays
and inlets of the coast swarm with swans, geese, ducks,
curlews, and most of the other ordinary wading and s-ting
birds. Large numbers of white pelicans frequent the
coast, and are sometimes shot, measuring 10 or 12 feet across
the wings. The coasts and rivers of California alike yield an astonishing
number and variety of fish. In some of the rivers as high as 30
feet are caught, and many of the salmon are 30 lbs
are often taken in a single day. Salmon-trout
and trout also largy abound. S'urguns are sometimes taken
in the mouths of the rivers measuring 8 or 10 feet long and
weighting nearly 500 lbs. Mackeral, pilchards, and sardines
are also found in the rivers. In the sea, cuttle-fish are
caught. Oysters of excellent flavour and most other
shell-fish are found. But though fish is so abundant,
the fisheries are at present little heard.

Climate, Soil, Agriculture, &c.—California has a dry and
a wet season; the dry season lasting from about the middle
of May to September or October, the wet season setting in early in November and lasting till May. But there are con- siderable variations, both in the temperature and in the
amount of rain, according to the position of the place in country. In its northern part, north of 39° N. lat., for example, the air during the dry season is much less parched and
rainy than in the south. The climate of California is much more temperate than in the great western part of the United States. Winter is mild, the heat never especially hot and parching. In the summer the coast is visited by heavy fogs, and a cold wind sets in regularly towards noon from the Pacific, and continues to blow with increasing
force and keenness late at night. Some few miles inland
the cold is modified, and the temperature is considerably
andagreeable. Throughout the great valley of the Sacra-
mentso and San Joaquin, the mid-day heat is so great as to render labour in the open air everywhere unpleasant, and in many parts insupportable.

The soil along the great valley is generally extremely rich. This valley has evidently been at some remote period the bed of a vast lake, and the rich alluvial soil only needs judicious irrigation to render it capable of producing almost every variety of coap. The banks of the rivers however require proper embankments to prevent the present often destructive floods, and to permit the full development of its agricultural capabilities. Tobacco, rice, maize, and most of the plants
above mentioned, are also possible in the United States, cotton which grow in the warmer parts of the United
States, are impossible in California, and cannot be sheltered without great expense. The climate is in
favour with this principal valley, while in the main valley itself
most of the cereals produce extraordinary crops, and grapes, peaches, and nearly all other fruits of a moderately warm climate are produced with a luxuriance and nutritiveness, affording excellent preservation for cattle. Nor
toh 39° N. lat, are extensive forests of pine and oke. The
valleys along the coast produce all the cereals, and all or
nearly all of the fruits and vegetables of the temperate and
cold parts of Europe. Oranges are grown in large quantities;
the produce from nine counties in 1852 was returned at
5,553,655 lbs. Tomatoes are extensively cultivated in parts of
the great valley; 1,039,900 barrels were raised in 1852 in
SACRAMENTO county alone, and in the same county 385 acres
were planted with melons. In the county of Santa Barbara,
the southern part of the coast, 1,370 barrels of olives were gathered; and in this and the adjoining county of Los Angeles 78,462 gallons of wine, and 73,056 gallons of brandy
were made. Agriculture has however hitherto been com-
paratively neglected, but as more attention is being paid to the
various capabilities of the soil are becoming more
apparent, and there will be little doubt that California is destined to take a high rank as an agricultural country.
cultivates more than three fourths of its sister-states; in what it surpasses ten of the states; of maize it produces less than any other; of grazing it has the greatest extent, and grows one fifth of the produce caused by the rest of the Union; in beans it surpasses nine of the states; in hay, though only half of the counties made return, it surpasses nine states; and in fruit it excels all the states in variety, and many in quantity. At the general new town, it includes one third of the state; of mules 26; of milch-cows 12; of work-cows 8; of sheep 4; and of swine (though the returns of both these are very imperfect) 3. In live-stock it surpasses 22 of the states, though in quantity the half of the states. The number of horses returned in the state in 1852 was 64,772, mules 16,674, cows 104,379, oxen 344,457, swine 82,867, hogs 39,976, poultry 96,530—the last three the returns are from only 24 counties. The total property of all kinds, and the commerce of the State of California, is partly shown by the statement of the number and tonnage of the vessels which entered and cleared at San Francisco in 1862:—

Entered—Sailing vessels of 326,138 tons. Steamers — 137 118,676

Total 1003 445,014

Of these, 40 vessels of 18,286 tons burden were British, and 59 vessels of 72,838 tons were Spanish.

 Cleared—Sailing vessels 1333 of 336,092 tons. Steamers — 158 127,047

Total 1491 483,139

Of these, 1121 vessels of 361,166 tons burden were American. In 1849 the tonnage of the vessels entered at San Francisco amounted to 313,361 tons, of which 247,417 tons belonged to the United States. The number of passengers arriving at San Francisco in 1849 was 41,700. In the year ending December 29, 1859, there arrived 64,190, of whom 3223 were females; and there departed 22,946, of whom 390 were females.

Of the manufactures we have no very exact account. At present the manufacture is chiefly for the market of labor and the superior demands of other branches of industry, the articles manufactured are chiefly such as cannot be profitably imported. Bricks for example are now made in immense quantities to meet the enormous demand for new buildings: the county of Marin alone reported to the census agents the manufacture of 1,500,000 bricks a month during 1862, of the value in the year of 300,000 dollars; the total population of Marin county during the same year was only 10,000.

Divisions, Towns, &c.—The state is divided into 25 counties. The original capital of the state was San José, next Vallejo, afterwards Hacienda; it is now Sacramento City. The chief town is San Francisco (S. F.), on the bay of the same name; to it there are 17 miles by water. SACRAMENTO CITY (S. F.), the capital of the "digging." Numerous other towns and "cities" have sprung up in various parts of the state, but most of them are built only of wood, or even canvas, and many of them disappear as rapidly as they arose. The following are among the more important and may require a brief notice:—

Stockton, on the Stockton Slough or Canal, formed by the junction of the Sacramento and San Joaquin rivers, 100 miles E. from San Francisco by water, was founded in 1849. Population about 5000. It is the port of the southern mining district and of the valley of San Joaquin, and is likely to remain one of the first towns in the state. Vessels drawing 9 feet of water can discharge their cargoes alongside the shore. Steam-boat communication is maintained with San Francisco. At present there is no public building of any consequence except an asylum for the insane. SAN JOSÉ, population 1200, the original capital of the state, is pleasantly situated near the south extremity of San Francisco bay about 50 miles S. from N. of number of horti it has some trade, but is chiefly agricultural. Near this town is the principal quicksilver mine. VALLEJO is situated on the Napa Srait, 25 miles N.E. from San Francisco. It is merely a small village. BENICIA is an important village on the west side of Suisun Bay, about five miles E. from Vallejo. MONTEREY, population about 1600, on the south side of Monterey Bay, was one of the largest and most frequented towns of Upper California prior to its cession by Mexico, and will eventually become an important commercial place when the fine bay on which it stands is resorted to, as no doubt it will be, by shipping. At present being away from the mining districts it is comparatively deserted. SAN DIEGO is another interesting town which the great river may doubtless again grow into importance. It stands on the safe and spacious bay of the same name near the southern extremity of the coast. Coal has been found near it.

Marysville, on the Yuba, 90 miles N.E. from Vallejo, is a town of 3444 people in 1854. It is the seat of Yuba county court, the county seat of Hardin county, and the residence of the legislature. It is the most important town of the north and east. The stores, two newspapers each having 'tri-weekly and weekly issues,' and nearly 8000 inhabitants, ORIO CITY on the Feather River, the capital of the Placer mining district, has the population of 6000 inhabitants. This district is mainly among the mountains. San Francisco, was one of the oldest and most flourishing of the gold district towns, but the 'diggers' have deserted its neighbourhood, its newspapers have ceased to be published, and the place itself is worn out and fallen into decay. In 1852 its population was 40,000, but at present it is a state prison is at San Quentin, 15 miles from San Francisco. Among the other towns which either have been, or are expected to be flourishing and important places, it must be office to name Auburn, Downieville, Los Angeles, Mariposa, Napa, Nevada, Santa Barbara, Santa Cruz, San Luis Obispo, Shasta, Sonoma, Suisun, Tuolomne, Vernon, and Yuba: in all of these the population is constantly shifting, and a statement perfectly correct to day would be wholly inaccurate in a month or year.

Government, Justice, &c.—The constitution of California resembles in its general features the constitutions of the other states of the Union. Slavery is not permitted. The legislative power is in a General Assembly, consisting of a Senate of 26 members elected for two years, and Representatives of 36 members, el-ct-d for one year; the sessions of the General Assembly are held annually. The governor is elected for two years; his salary is 6000 dollars a year. The receipts for the year ending June 30, 1856, were 723,269 dollars; and expenditure 503,943 dollars; the balance was 1,366,648 dollars. The total debt of the State, Jan. 1, 1857, was 4,128,927 dollars.

The judicial power is vested in a supreme court and district and county judges throughout the state. The court consists of a chief justice, who has an annual salary of 6000 dollars, and two associate justices, each of whom has a salary of 6000 dollars a year. The justices are elected by the people for six years; and are re-elected until they are compelled to retire by age. The senior judge in office is the chief justice. The first judges of the district courts were chosen by the legislature, but all future judges are to be elected by the people: there are fifteen district judges, with annual salaries varying from 2000 to 3000 dollars. A county-court judge is elected in each county for four years.

The constitution directs that a superintendent of public instruction shall be elected, to hold office for three years; and that the legislature shall establish public schools, in which instruction (except during the first year) shall be free; and it also provides funds for their support. A Board of Education has been established, and the returns for 1856 from all but four counties exhibit 322 districts, 417 teachers, and 29,628 scholars from 4 to 14 years of age. HISTORY.—California was discovered by Cabrillo in 1542. It was next visited in 1576 by Sir Francis Drake, who named it New Albion. It was first colonised in 1768 by the Spaniards, who established in various places, chiefly west of the Coast Range, military posts (presidios) and religious stations (misions). There were four of these military stations and twenty-one missions; and while California remained subject to Spain the actual direction of the country was in the hands of the priests, the governor having scarcely any civil authority. The priests collected the native Indians in villages, and taught them to cultivate the soil, but gave them little other instruction either religious or secular. According to the latest account published by the priests there were above 18,000 of these modestly converted Indians,' besides 3000 more of the same persuasion. At present the missions from Spain the missions were broken up, and the Indians returned generally to their native state. After the declaration of Mexican independence a good many of the early settlers in California visited California for the purpose of hunting or trading, and several Americans settled in the neighbourhood of San Francisco. The government appointed by Mexico were unable to maintain tranquillity in the province, and the government increased still, in 1836, it issued in A successful revolt, mainly excited it is said by the former residents. The government was overthrown without blood-
shed, and the governor and other officials were put on board a schooner and shipped off to Mexico. The Mexican government ordered the Californians either to go to Mexico or to stay in their own country, and the country continued nominally subject to Mexico. It remained however in a state of anarchy, and for some time before its cession had become virtually under the control of American citizens. On the termination of the war and the entry of the United States California was, as already mentioned, formally ceded to the United States by treaty in February, 1848; and on its rapid growth in wealth and population, consequent on the gold discoveries, it was a year or two later admitted into the Union as a sovereign state.

(C.1von, Statistical Gazetteer of the United States, 1853; American Almanac; Fremont, Wilkes, and various Travels, Journals, &c., in California; Visits to Gold Diggings, &c.)

C. ONOM AT Y. A group of plants belonging to the natural order Polygonaceae, of which one species, C. Pallisia, yids in its roots a amlycousyummy matter, on which the Calmucks feed in times of scarcity. The fruits and branches are acid, and are chewed by the same people to allay their thirst. This plant is destitute of leaves, and grows in great abundance on the sandy steppes of Siberia.

CAMERWELL, [Surrey.]

CAMBorne [Cornwall.]

CAMPACK, of the River Loyal, 23,410; also the HAROENS, a river of Africa, which discharges itself into the Bight of Biafra and into the same maturies as the M-limba, about 45 miles from Fernando Po. It has a bar across its mouth, with an average depth of from 15 to 16 feet water over it. Of this river little is known beyond its entrance into the river. On the coast of this coast, it has been long known to be a great mart for slave. Palm oil and ivory are obtained here; the latter is considered very fine. The system of tr-flic is by barter. This river is navigable from those to the mouth by high land called the Campon Moroboines, the highest strata of which rises to 13,000 feet above the sea, and is generally capped with snow. The name is derived from the Portuguese word for shrimp, of which the is a great abundance.

Each strip of land was ceded by a section of the chief, whose friendship must be purchased by presents before any traffic is commenced.

CANDID, CHIPPING. [Gloucestershire.]

CAM-PHOARA, a genus of plants belonging to the natural order Lauraceae. This genus was constituted by Nee von Esenbeck for the Laurus Camphorifera of Kampfer, the plant which yids the Camphor of commerce. It is known by its hermaphroditic panicked flowers, 8-cleft papery calyx, a large orbicular involucre; 3-fertile, the inner row with two stalked glands at their base; the anthers e-rolled, the outer turned inward, the inner outward; the fruit placed on the obconical base of the calyx; the leaves triply serrated, glandular in the axis of the principal vein near its base.

Coffeiinum, the Camphor Laurel, is a tree with lax smooth branches; the leaves are bright green and shiny above, piler beneath, and somewhat coriaceous, with a sunken gland at the axis of the principal veins, projecting at the upper side, opening by an oval pule on the tooth. This plant is a native of Japan and China, and is cultivated in most of the warmer parts of the world. The Camphor of commerce is yied by this tree, which is cultivated most extensively in the island of Formosa, from whence it is taken to Canton, which is the principal market for Camphor. [Camphor.]

CAMPION. [Lychnis, S 1; Silene.]

CAMPBELL. [Stirling] .

CANADA.—Lower Canada, or Canada East, is divided into 64 counties, the names of which we give here with the population of each in 1851.—Bechscaroia, 40,213; Belle- chese, 17,982; Bertheir, 34,918; Bonaventure, 10,844; Chambly, 20,576; Champlain, 13,896; Dorchester, 43,105; Drummond, 16,562; Ech, 10,360; Huntingdon, 40,645; Kamouraska, 20,366; Lake Placid, 29,690; L'ile de l'Orme, 17,089; Lotbiniere, 16,587; Mégantic, 13,385; Missisquoi, 13,484; Montmorency, 9,928; Montreal, 77,381; Nicolet, 19,667; Ottawa, 28,923; Purtneuf, 19,396; Quebec, 61,512; Richer, 15,231; Richmond, 19,671; Robinson, 22,093; St. Bonaventure, 20,783; St. Maurice, 27,662; St. Hyacinthe, 30,623; Sherbrooke, 20,014; Steffee, 16,428; Stanstead, 13,898; Terebonne, 26,791; Two Mountains, 30,470; Vaudreuil, 21,297; Warden, 29,920; Yamaska, 14,745; total population of Canada East, 890,261.

In Canada East are Montreal and Quebec. [Montreal.]

QUASA.] The other towns are Three Rivers, St. Hyacinthe, Sherbrooke, and Sorel. Three Rivers is prettily situated at the mouth of the river Water, and has a population of 3,000 and has a population of 4,936. There are iron mines near the town. There is considerable industry of pot- and pearl- ashes. Three Rivers is one of the depots of the north- west traders, and is on the whole a place of some im- portance. Sorel, population 4,941, is situated on the river St. Lawrence, is likely from its advantageous situation to be of much greater importance than it has yet attained. By the Chambly Canal there is communication between Lake Champlain and the St. Lawrence, at Sorel. There is also a railway along the same line of road.

Upper Canada, or Canada West, is divided into 42 counties, as follows,—Adinburgh, population 15,165; Brant, 25,485; Bruce, 26,237; Carleton, 51,397; Dundas, 13,611; Durham, 22,892; Essex, 30,735; Grey, 13,517; Glengary, 17,596; Grenville, 20,707; Haldimand, 18,788; Halton, 18,322; Hastings, 31,577; Huron, 10,198; Kent, 17,469; Lambton, 18,105; Lanark, 27,317; Leeds, 30,380; Lennox, 7955; Lincoln, 23,668; Middlesex, 22,587; Norfolk, 16,206; Northumberland, 21,281; Ontario, 30,576; Oxford, 33,683; Peel, 24,816; Perth, 15,545; Peterboro, 15,537; Prescott, 10,457; Prince Edward, 18,587; Renfrew, 9415; Russell, 2870; Simcoe, 25,954; Stormont, 27,007; Wellington, 26,798; York, 79,719; population of Canada West, 902,004. Total population of Canada, 1,842,866.

Canada West contains the cities of Toronto, at pre- sent capital of the Canadian government, and the chief town of the colony, and Kingston. [Toronto.] Hamilton is beautifully situated at the western extremity of Burlington Bay, near the shore of Lake Ontario. It was founded in 1813, and became an incorporated town in 1839; the population in 1831 was 14,112. The construction of the Burlington Canal, a short cutting which opens a direct navigation into Lake Ontario, and the improvements of the Desjardins Canal, five miles long, which connects Hamilton with the manufacturing town of Brantford, and which are nearing completion, add greatly to the commercial value of the city. It is the district town of Gore district, and as such contains the court-house for the district and other public buildings. The streets are well laid out, and many of the houses are built of stone. There are two market-houses, one of them being a pretty little rural style used as a depot for mail and other goods, located in a well-furnished house, a post-office, and a theatre. The are places of worship for Episcopalians, Presbyterians, Wesleyan Methodists, Independents, Baptists, Roman Catholics, and others; news-rooms; and a mechanics institute. Good roads extend in all directions from the city, and numerous stage-coaches set up communication with the surrounding districts. Steamboats ply regularly during the season to Toronto and to Queenstown and Niagara. Hamilton has much increased in importance; it contains a large and populous population, and is growing into a city of importance. The city is situated 19 miles from Hamilton, and is a healthy place.

The towns of Canada West the following may be noticed:—Ankermuir, a garrison town on the Detroit
River, population 1880, is finely situated, the banks of the river in the vicinity of the town being very beautiful. The town received in 1842 a charter to hold a fair twice a year.

There are Episcopal, Presbyterian, Methodist, Baptist, and Roman Catholic places of worship, a court-house, news and reading-rooms, and a market-place. British and American newspapers are published in the town, and there are in the neighbourhood of the town. Bariage, population 1207, commenced in 1823, is now the district town of Simcoe district. There are in the town a court-house, a workhouse, a jail, and a few other public buildings. Steam-vessels ply on Lake Simcoe, which by the river Severn communicates with Georgian Bay and Lake Huron. Befellite, population 4693, situated about 50 miles W. from Kingston on the Bay of Quinte, is a place of considerable importance. It was reported in the census of 1831 that there were 690 people in the district of Victoria, several places of worship, and some other public buildings. Steam-vessels call regularly at Selville. Brantford, population 3577, on the left bank of the Grand River, about 74 miles W. by S. from Hamilton, was commenced in 1829. A canal about 24 miles long with three locks enables vessels of moderate draught to reach the town; thus avoiding the falls of the Grand River. There are chapels for Episcopalians, Presbyterians, Independents, Methodists, and Dissenting sects. There are a large dwellings, houses, saw-mills, soap-factories, and other establishments give considerable employment. Brockville, population 3246, situated on the river St. Lawrence, about 56 miles N. E. from Kingston, was founded in 1802; it is now an incorporated town, with a population of 1037. It possesses a handsome appearance. The court-house and jail, and the churches, of which there are several, are stone-built. Tanneries, saw-mills, a brewery, and other works employ some of the inhabitants. Steam-vessels frequent the river Thames, population 5743, on the left bank of the river Thames, 60 miles S. W. from London, and 50 miles E. from Detroit, is a thriving town, with an increasing trade. A canal about 18 miles long between Kingston and Brockville, with communication with Detroit and Amherstburg. There are here saw-mills, tanneries, pottery works, &c. Several places of worship in the town. Cobourg, population 3871, is situated on gently rising ground, on the bank of Lake Ontario, 103 miles W. by S. from Kingston, 72 miles E. by N. from Toronto. The town is well built, and has a good appearance. The harbour and lighthouse are of recent construction. There are churches for the leading denominations of Christians, a court-house, a mechanic's institute, &c. Victoria College, about 15 miles from the town, is maintained by the Wesleyan Methodists, but not exclusive in its management, is supported partly by a legislative grant. It has the power to grant degrees. There are here a large cloth-factory, mills, and other works. Cesare, population 2070, on the right bank of a branch of the river Thames, 14 miles S. of Cobourg, is the Cornwall Canal in the St. Lawrence, was incorporated in 1834. There are many good stone dwelling-houses, several churches, and a court-house and jail. Some tanneries, a foundry, and other establishments give employment. Dundas, population 3417, a manufacturing town, about 8 miles N. W. from Hamilton, possesses extensive water-power, which has contributed much to its prosperity. The town is surrounded on three sides by high table-land, usually termed the "mountain"; by this high land freestone and limestone are procured and exported. There are several churches in the town. There is a mechanics' institute Goderich, population 1329, on Lake Huron, at the entrance of the Maitland River, was laid out in 1827 by Mr. Galt, who subsequently procured a charter. The town is finely situated on rising ground, more than 100 feet above the level of the lake. It is about 60 miles N. by W. from London. An expensive harbour was constructed, and a light-house was placed at the point but the town has not yet proven successful. There are several churches, a court-house, breweries, tan-yards, &c. Guelph, population 1869, the district-town of Wellington district, about 42 miles N. W. from Hamilton, was laid out by Mr. Galt in 1828. It is pleasant and healthy; and the houses frequently at the point but the town has not yet proven successful. There are several churches, a court-house, &c. Hamilton, population 1850, is finely situated at the junction of two branches of the river Thames, about 56 miles W. by S. from Hamilton. It was commenced in 1822, and subsequently extend to 1840. London suffered severely from fire in 1844 and 1845, but the appearance of the town was much improved by the handsome streets of fine buildings which were subsequently erected. St. Paul's Episcopal church, erected by subscription to replace the edifice burnt down in 1844, is a beautiful gothic structure with a square tower surmounted with pinnacles. The court-house and jail, built of brick in the form of a castle; commodious barracks; two market-buildings, &c., are admirable. The North shore railway are among the public buildings of the town. There are good roads in the vicinity. Machine-making, tanning, brewing, &c., are carried on. Niagara, population 3840, the district-town of the district of Niagara, is one of the oldest towns in Canada, and was for five or six years under the name of Newark the capital of the country. It has several churches, a town-hall, and a court-house. The Niagara Harbours and Dock Company, incorporated in 1820, have constructed a number of good vessels, and the town is supplied with a few miles from the town. Peterborough, population 2191, occupies a beautiful situation on the Otonabee or Trent River, about 34 miles N. W. from Cobourg. It was commenced in 1826, is well laid out, and has a handsome appearance. The court-house and jail, and the town is called Peterborough East. Most of the places of worship are built of stone. On an elevated site behind the town is the court-house and jail, a handsome stone edifice.

There are here woolen manufactories, fulling-mills, saw-mills, chair-factories, breweries, &c. Picton, population 1452, chief town of Prince Edward district, is finely situated on the Bay of Quinte. It is an old town and contains many good stone houses. Steamers call here on their passages around the world. There are several places of worship, a court-house, a jail, and a library. A good deal of trade is carried on. Wheat, flour, leather, &c., are exported. Port Hope, population 2478, on Lake Ontario, about 8 miles W. from Cobourg, between Toronto and Kingston, is built on the site of a rich commanding interesting views of lake and inland scenery. It contains some handsome buildings, including four places of worship. Wheat, flour, and timber are the chief exports. Prescott, population 2156, on the S. W. Lawrence, about 12 miles N. E. from Brockville, possesses considerable trade previous to the opening of Rideau Canal, but since then it has not made rapid progress. Among the buildings are four places of worship and a custom-house. At this place the river is nearly broad, and the whole river is covered with green pelts as is exported. Sandwich, population not given, at arately, on the Detroit River, is finely situated and well laid out. It is one of the oldest towns in Canada, and has assumed very much the appearance of an English country town. Many flower-gardens and orchards are kept by the inhabitants. The Episco-palians and Methodists have places of worship in the town. Simcoe, population 1459, the chief town of Talbot district, is situated near the shore of Lake Erie, about 34 miles S. S. from Brantford. Grist- and saw-mills, a carding-machine and fulling-mill, with other establishments, furnish employment. St. Catherine's, population 4368, on the Welland Canal, about 12 miles W. from Niagara, occupies a beautiful situation, and possesses a good situation. Shipbuilding is in a flourishing condition, and the flour are annually exported. There are six places of work. Woodstock, population 2112, chief town of Oxford county in the Brock district, about 32 miles S. E. from London, is pleasantly situated. It is connected by the London and Woodstock, forming one street of about a mile long. There are six places of worship, a court-house, and a mechanics' institute. Considerable trade is carried on.

Of the population of Canada East, 638,261, as many as 690,261, are English, 184,261, are Irish, 132,500 are Canadians of other than French origin; 61,400 are of Irish origin; 14,505 of Scotch; 12,482 are from the United States of North America; and 11,230 from England and other British colonies. It is composed of the colonies and the colonies of the European continent, and of our own colonies.

In Canada West, the population of which is 952,004, the Canadians of French origin number 28,417, and the Cana-
dians not French, 536,093; the Irish, 176,267; English and Welsh, 82,699; the Scotch, 75,811; natives of the United States, 4,732; Batavi, 985; and Batavian refugees, 6,067. With respect to the whole of Canada, of which the total population is 1,842,263, the seven principal items stand as follows:—Canadians of French origin, 695,945; Canadians, not French, 561,673; Irish, 227,766; English and Welsh, 93,567; Dutch, 75,653; British subjects of the United States, 65,214; of Germany and Holland, 10,116. At the time of the surrender of Canada to Great Britain, the population was chiefly French, and located in the lower province. Although this class has not been much increased by immigration, it now amounts to about 1,000 per cent. The progress of Canada West has been still more remarkable. In 1791, the population was 150,000; in 1811 it was 77,000; in 1824 it was 61,007; in 1832 it was 261,060; in 1842 it was 488,005; and in 1851 it amounted to 958,004.

The amount of immigration into Canada is stated in a separate article. [Emigration, S.2.]

In January 1857, the total length of main railways in Canada was above 1,000 miles. These railways consist of two principal lines, the Grand Trunk Line and the Great Western Line, which are united at Toronto, and form a continuous railway from St. Thomas, east of Quebec, to the western boundary of Canada, or Detroit River. The Grand Trunk Line proceeds from St. Thomas 60 miles to Niagara, 22 miles to the Niagara Falls, 17 miles to Hamilton, 24 miles to Toronto, 34 miles to Lake Huron, 138 miles to Lake Superior, 17 miles to Sault Ste. Marie, 170 miles to Thunder Bay, 24 miles to St. John, 40 miles to Quebec City, 70 miles to Montreal, 90 miles to St. John, 117 miles to New Brunswick, 70 miles to Fredericton, and 100 miles to the Sea. The Great Western Line extends from Toronto through Hamilton and Chatham, to Windsor, opposite Detroit, 229 miles. There is also an independent line from Niagara Falls to Hamilton 34 miles. This gives a total length completed of 903 miles, exclusive of the Ottawa branch and other smaller railways.

The revenue and expenditure in each year, from 1845 to 1853, are as follows:

Canada receives from the United Kingdom coal, metal, cordage, East India produce, and the various kinds of British manufactures; from the British West Indies, sugar, molasses, coffee, rum, and hard woods; from the United States, beef and pork, biscuit, rice, and tobacco. The exports of Canada are:—To the United Kingdom, pot and pearlash, wheat and flour, and timber; to the West Indies, beef and pork, beer, grain, and flour; to the United States, forest produce, wheat, flour, butter, wool, livestock, &c.

CANNABINACEAE, Hempseeds, the Hemp Tribe, a natural order of Exogenous Plants. This little order, which has been separated from Urticaceae embraces two well-known families, the Haploa (Haploa lutea) and the Haploa Carallus satis). They are distinguished from the Nettle Tribe by having a solitary suspended ovule, and a hooked ex-albuminous embryo, with a superior radicle. [Humulus; Cannabis.]

CANON LAW. In the university of Oxford, the com- mons have been authorised to sit for the six years off-stet at 17 & 18 Vict. c. 81, s. 45. The canon law still governs the court of the university of Cambridge.

CANTINE. [Anvul, 1837.]

CANTON, WAR AT. [China, S. 2.]

CAPELLEN, GODFRED ALEXANDER GERARD PHILIP, BARON VAN DER, a distinguished governor-general of New South Wales, was born at Utrecht on the 15th of December 1778. He lost his father, Philip van der Capellen, Heer van Berkenwonde, before he was nine years old. After studying at Göttingen under Mar- tens and Blumenbach, with both of whom he continued in correspondence, he entered the service of Holland, and became in 1809 Minister of Internal Affairs under King Louis Bonaparte, whom he strongly advised to defend the entrance of Holland by force against the armies of Napoleon, and when the French system was introduced into the Netherlands, he was one of the first to advise his retreat at Oratza. A coolness however arose on the part of the ex-king when he found that his late minister looked with no unfavorable eye on the rising in Holland to restore his ancient liberty, and after the complete evacua- tion of Holland from the French yoke, Van der Capellen was in fact appointed Minister of C-merce and the Coloni- es, and on the 1st of August 1814 Governor-General of the Dutch East Indies. Owing to an important mission to the congress of Vienna, and the departure of Napoleon, which gave Van der Capellen an admirable opportunity of showing his constancy and courage at Brussels on the day of Waterloo, he did not leave Europe for his post till October 1815, and a further delay occurred before he finally received the appointment from that period, the government assumed the administration of the country. He remained beyond the five years, which had been originally intended, and was recalled in disgrace in 1816, when he was universally censured in Europe for the part he had taken in the renewal of the war. His return to the Netherlands was a triumph, he entered the States at Calcutta, at nine per cent, on the security of the revenues of the Dutch East Indies. It was said that all of these that could be adopted the most unavoidable was that of pledging the Dutch possessions to the English. Van der Capellen had however shown no prudence; he had, on the contrary, strongly urged the Dutch government not to consent to the English establishment of Singapore. He had however followed up the arrangements made by Sir Stamford Raffles during the English possession of Java, and by that measure immense improvement was effected in the position and prospects of the country. He had also abolished the monopolies which under the old Dutch system pressed heavily upon the natives of C-ehes and the Moluccas, made alterations and improvements much required in the state, and taken measures for the abolition of the slave trade and slavery. The most unfortunate circumstance connected with his administration was the outbreak of the great revolt of Diego Neureo, a Javanese chief, which lasted many months and which spread from the East Indies to the home state of Java. On the whole, however, when his administration came to be reviewed, the unpopularity which had collected around him gradually cleared off, and his merits are now universally acknowledged. He was nominated for several high posts, among others to that of ambassador to England on the occasion of the Coronation of Queen Victoria, President of the Commission of Education, and President of the University of Utrecht. In February 1848 he was unfortunately on visit to Paris, on an invitation from King Louis Philippe, who was a personal friend when he was on the outbreak of the revolution he was struck on the head by a stone thrown by one of the mob. No outward injury appeared, but on his return to his seat at Volkheuven he sunk into a deep melancholy, produced partly by his feelings at the events he had witnessed and this was succeeded by an inflammation of the brain, which carried him off on the 10th of April, 1848.

CAPPOQUIN. [Watersford.]

CARAPA, a genus of plants belonging to the natural order Meliaceae. C. Toulouwouhna yields the Talloowouh or Kundar Oil, which has a reputation as an antihelminthical. It is said to be well suited for burning in lamps. The bark of the root of C. obovata is bitter and astrigent. The bark of C. Gu- mmosa is also used as an antihelminthical and febrifuge.

CARBUNCLE. [Gnænaet.]

CARDIOSPERMUM, a genus of plants belonging to the natural order Sapindacea. The root of the one species, C. cardiospermum, is an emetic, diaphoretic, and antipyr- ent. In the Moluccas the leaves are cooked and eaten.

CARDIUMA. [Conchacka.]

CARDUELIS. [Golfinch.]

CARIA. [Karia, S. 2.]

CARLINGFORD. [Lothv.]

CARLOS, DON (Comte de Molina), Infante of Spain, and
the Spanish throne, was the second son of Carlos IV of Spain, and was born on the 29th of March 1788. Left chiefly in the hands of priests, to whom the superintendence of education had been entrusted, Don Carlos remained in comparative obscurity during the domination of Godoy. On the first abdication of his father and the accession of his brother Ferdinand VII, Don Carlos was sent to meet Bonaparte, who had announced his intention to visit Spain. The young prince, including General Castanos in his retinue, was made in effect a prisoner, and Ferdinand, like his brother, soon found himself also in the hands of the French. Bonaparte next compelled the weak ex-monarch of Spain to proceed to Bayonne, and refusing to acknowledge his former aberrations, required him to abdicate in favor of his own son, Louis XVIII, to whom he offered the crown for himself and his posterity, to "abridge all claims to the Spanish kingdom in favor of his ally the Emperor of the French." In this renunciation, after a strenuous opposition, Don Carlos, as well as Ferdinand, was compelled to join. The brothers were sent to Prince Talleyrand's house at Vallençay, where they were detained prisoners, though treated with great respect, till 1813, when Napoleon restored them to liberty, and Ferdinand to the throne of Spain.

When, after the suppression of the constitutional party by the French invasion under the Duc d'Angoulême, Ferdinand appeared inclined to adopt a somewhat more moderate policy, the absolutists turned their attention towards Don Carlos, and demanded his restoration. The counsels of a formidable character was organised, and an insurrection broke out in Catalonia in 1805, but was repressed by the vigorous measures of the Count of Espana.

Don Carlos had himself taken no open share in the insurrection, according to his principles, in favor of his brother's throne, and it is probable he was anxious not to endanger his succession by a premature declaration. His hope of legal succession was however quickly dispelled. Ferdinand had been three times married without having any children, but by his fourth wife, Dona Maria Isabella, he had in October 1809 a daughter, Isabella, the present queen of Spain. By the ancient laws of Spain females could inherit the crown in default of male issue; but the Salic law of France had been so long disregarded as to be almost forgotten. Ferdinand, excluded from the throne till 1812, when Carlos IV abdicated the restriction, and restored the ancient rule of succession. In 1812 however the Cortes re-established the Salic law, and Don Carlos was therefore still the heir-presumptive to the throne. But Ferdinand now issued a decree which annulled the provision of the Cortes, and restored the order of succession in the female line. Don Carlos protested, but remained quiet. His partisans however throughout the kingdom prepared for the big ligue, and it might have been distantly seen.

In September 1833 Ferdinand was believed by himself and those about him to be dying, and the feebile king, terrified at the mischiefs which he was assured would result from the disposal of the crown to his son, wrote to Castanos, after obtaining the advice of his favourite minister Calomarde, signed a decree by which he restored the Salic law. Ferdinand however rallied, and was easily induced by his sister-in-law to destroy the evidence of his recent vacillation. He died a few days later, and his death was the signal for a general rising of the adherents of Don Carlos in opposition to Queen Isabella, who had succeeded to the throne of her father.

For full five years Spain was desolated by a civil war, in which at one of the most unfortunate battles which has ever disgraced a civilized country. Spain was supported by the great body of the priests, by a large portion of the country party, and by nearly the whole of the inhabitants of the Basque Provinces—the bravest and most devoted portion of the Spanish people. Had he been a man of more energy and ability, the great probability is that he would have succeeded. But he possessed in full the hereditary bigotry, weakness, and obstinate folly of his race, and he more often marked the narrow limits of his general character. Yet the energy and courage of his genera's, Cabrera and Zumalacarregui, maintained the balance decidedly in his favor, till the valuable aid of the British legion under General Sir de Lacy Evans, and the death of Zuniga, which caused the retirement of the Basque Provinces from the service of the Crown, and the surrender of his army to Espartero in August 1839, left Carlos no alternative but flight, and he at once took refuge in France.

Louis Philippe assigned him, a residence in the city of Beuges, where he was joined by his family, and where for some years he maintained a mimic court, in which was observed all the elaborate etiquette of the Spanish monarchy. At length, sick of hope deferred, he in 1845 formally relinquished his claim to the Spanish crown in favor of his eldest son Don Carlos Luis Maria Fernando, Count de Montemolín. The abdication of Don Carlos was strongly opposed by his wife, the Princess Maria Theresa (daughter of John IV. of Portugal), and by his leading supporters, including General Castanos in the hands of the Queen-en; and the subsequent rising in favor of the Count de Montemolín was easily suppressed. Don Carlos was permitted in 1847 to remove to Trieste, where he remained in strict retirement till his death, March 10th, 1856.
FCAS

Ferdinand, who was very fond of him, circulating amongst the lower classes. Among other posta of dignity, he held that of the shrine of the Virgin, the patron saint of Madrid, which he died at Madrid, on the 24th of September, 1858, and his remain were honored with a public funeral.

CASTEL VETRANO, a town in the province of Trapani, in Sicily, is situated near the left bank of the Dania, 10 miles E. of Castellammare, and is a notable one of the most ancient in Sicily. It is situated on the 30th mile of the road from Palermo to Trapani, about 6 miles from the nearest point on the south coast of the island, and has a population of about 13,000. The town is famous in works in coal and alabaster. It is built on a hill, and is an old fortress, with an ancient wall, several gates, columns, and palaces. The country round Castel Vetrano is fertile in wine and rich pastures. A few miles from Castel Vetrano, to the south-eastward, are the ruins of the ancient Selinunte. This ancient site is covered with broken columns, capitals, and fragments of the Doric, and of large dimensions; they are called 'Giante Pillars' by the peasantry. Some finely sculptured metopes were discovered at the base of the façade of the central temple in 1892. There are ruins of six temples in all.

CASTELLAMMARE, the chief town of a subdivision of the province of Napoli, in the kingdom of the Two Sicilies, is situated near the head of the Bay of Naples, on the lower slopes of the island of Monte Sant'Angelo, 15 miles by railway E.S.E. from Naples, and has a population of 18,000. It is connected by a branch railroad with the Naples-Nocera line, the first railroad opened in Italy. The town stands on or near the site of the ancient Stabiae, and is built on the slopes of the ancient Mount Vesuvius, in the eruption of A.D. 79. During this eruption Pliny the elder lost his life at Stabiae. The hill above Castellammare is called Monte Qui-si-sana from its being covered with vines and cypresses, among which is the latter is the royal casino of Qui-si-sana, founded by Charles II. of Anjou, and now the property of the Russian prince Leveen. Behind the hill rises the imposing mass of Monte Sant'Angelo, which will again be discussed; through the forested pines runs a road, and forms a conspicuous object between the bays of Salerno and Naples. The town derives its name (signifying 'castle by the sea') from its castle, which was erected by the emporor Frederick II., surrounded by walls and towers by Charles I. of Anjou in the 13th century, and subsequently strengthened by Alfonso I. of Aragon. The town was sacked by the army of Pius II. in 1461, and again in 1564 by the Duke of Guise. The harbour has a depth of three to four fathoms wide, it is 1,100 feet in length, and has three whitewashed mole. In connection with the harbour are a bagnio for galley slaves, and a royal arsenal and dockyard, where the ships of the Neapolitan navy are built. These establishments contribute materially to the prosperity of the town. Castellammare has a noted hospital and a public school. The waters of this town are famous for their mineral springs, which are very efficacious in gout and rheumatic affections. There are twelve of these—four chalybeate, four saline, and four sulphurous—and they all rise at the base of the Monte d'Auro, within a short distance from each other. They are all of moderate temperature, seldom exceeding 65° Fahr. Great numbers of visitors frequent Castellammare and its delightful neighbourhood during the summer and autumn; the temperature is 8 or 10 degrees lower than that of Naples. The town, which gives title to a bishop, and has a handsome cathedral, is well built, partly on the lower slopes of Monte d'Auro, but chiefly along a sheltered beach commanding a view of the whole bay of Naples. Here the wheat is exported; the chief imports are coal, timber, and machinery. Among the industrial products are maccaroni, silk and cotton goods, and salt-cloth. The fisheries along the coast employ a good many hands. Some excursions made among the ruins of Stabiae in 1748 brought to light a few fragments of faience, some pottery, and paintings, which are now in the Museum of Naples.

There is another Castellammare, or Castellamare, in the province of Trapani in Sicily. It is situated on the southern shore of the Gulf of Castellamare, 28 miles E. from the town above mentioned, and about 20 miles W. of Palermo; it has about 6000 inhabitants. The town, which is ill-built and dirty, is named from its old decaying castle. It carries on a considerable trade by sea, and has large granaries; the exports are wine, oil, and tobacco. The remains of the ancient Segesta are near Castellamare; they consist of a Doric temple in tolerable preservation, the ruins of
nearly the whole of a summer, engaged in the study. To
wards the end of this travels, which lasted for four years, from 1843
to 1849, he crossed the Tundras, or deserts of European
Russia, and also the mountain ranges which were not even the
rein-deer can from the wintry blast and live. Philosophy
has its martyrs as well as religion. Castrén returned with his
constitution poisoned.

While on his travels he had written most interesting and
anecdotes of his adventures and discoveries, which were published in the Svaomi, an excellent periodical in the Swedish
language published at Helsingfors. Many communications from him on learned subjects, chiefly written in
German, appeared at the same time in the Zeitschrift der
Sveicirischen Gesellschaft der Wissenschaften. His name was universally known as that of a philologist of the
first rank, but it was not till March 1851, on the occasion of a
visit of the Grand Duke Alexander, the present Emperor
of Russia, to the University of Helsingfors, that he was, from
the possession of a private document, or private tutor, to
that of professor of the Finnish and old Scandinavian lan-
duages. One of his duties was to deliver a course of lectures
on Finnish mythology, which he immediately commenced
composing, but before that he could be finished he was no more.
He died at Helsingfors on the 7th of May, 1858, from the
effects of his ruined journey.

The translation of the Kalevala, and some of Castrén's
other works, have been already mentioned. His lectures,
Veistä, or Finnish Mythology, were published in
Germany at St. Petersburg in 1853 under the editorship of
Schleifer. A German version of his travels by Helms was
published at Leipzig in 1856, and translated at some length in
the Quarterly Review. His other works were mostly of a
philological character, in which he was eminently noted;
and as such he ranks with the Finnish, the Swede, and
other dialects scattered over the surface of European Russia,
to investigate which was the object of Castrén's devoted
exertions. It is much to be regretted for the sake of learning,
as well as on other accounts, that he was snatched away
before he had time to communicate to the world the results
of his dauntless and ingenious labours.

Catalysis. [Chem. Trans. 1.]

CATARAQA, one of the upper provinces of the Argentine
Confederation, lying north and west of Buenos Ayres, is bounded
by the provinces of Tucuman, E. by Santiago, S. by Cordova,
and W. by La Rioja, and comprehends the little visited
country between the mountain ranges of the Sierra de Acon-
quejo and Ambato on the east, and the Andes on the west.
The climate is healthy, and the valleys are fitted for
agriculture, and the soil well adapted for vineyards.
Cataras, from which the province derives its name, and in
which most of the inhabitants are settled; and of some other
valleys, running between mountain ranges south-east and
north-west, and terminating at their
western extremities on the borders of the Gran Salinas, being
distinctly separated from the other inhabited countries by
high mountains and deserts. The rivers which water these
valleys are lost in the Gran Salinas. The climate is sultry,
especially when the suns winds blow, which come over the
desert. Malachite and other copper-bearing ores are found
in the province; but the copper is not easy to be
extracted from the copper oxide. The provinces sends
only cotton and red pepper (dried capsicums) to the adjacent
countries, the latter chiefly to Buenos Ayres, where it is
extensively used. The present capital is Catamarca, or Sem
Fernando del Palle de Catamarca, in 7° 25' S. lat., whose
population is stated to be 4000. The first capital, called
London, which was founded at the time when Philip II. of
Spain married Queen Mary of England, was destroyed by
the Indians.

CATHA, a genus of plants belonging to the natural order
Celastracea. C. edulis is the Kat or Khat of the Arabs. It
would appear," says Dr. Lindley, "to be of a stimulating
character. According to Forskal the Arabs eat the green
leaves of this plant. Dr. Lindley sees in it a very
powerful nerve cord, which may be stood as an antidote to
insanity, and as a person wearing a wig of it in his bosom may go among the
people with impunity; they even believe that the plague cannot
appear in places where the tree is cultivated." (Vegetable
Kingdom, p. 537). At the same time Forskal adds, "The
f Автор этою доскою не видел этого вида." (Catharine's, St. [Canada, S.].

CATHICART, LIEUTENANT-GENERAL THE HON.
SIR GEORGE, K.C.B., was born in London, on the 18th of
May, 1754, the son of William Shaw, the first Earl Cathcart.
He was educated at Edinburgh University, and entered the
Army in 1772, by appointment to the 3rd Light Infantry, and
in 1810 he began his military life by joining the 2nd Life
Guards. In 1812, by which time he had been promoted to
a lieutenancy, he was appointed to the command of the
Russian Forces in the province of Moscow, and when the Emperor
Alexander took the field in
person in 1813, Lieutenant Cathcart joined the imperial
Army. He served with the grand army throughout the cam-
panes of 1813 and 1814, witnessed the battles of Lutzen and
Bautzen, those of Dresden and Leipzig, of Brienne, Bar-sur-
Aube, Arcis-sur-Aube, and the taking of Paris. Of these
campaigns, and more particularly of the strategy of Nape-
olin, he has left an account, accompanied with diagrams showing the position of
the armies, with their movements. It is a valuable work;
an additional interest being given to it by an introduction to
the service of the Allied Powers, as well as of the French,
and displaying the skill and powers of national character under the different circumstances of
attack and defence. In 1814 he again accompanied his
father, who was one of the three plenipotentiaries sent to
Paris. On the 9th of March he was appointed aide-de-camp to the Duke of Wellington, and
was present at Quatre Bras and Waterloo. He was continued in
the appointment when the Duke became master-general of
the ordnance. He accompanied him on his mission to Algier,
aud to the Grand Duchess at Baden, and to Berlin. In 1812
he had arrived at the rank of Lieutenant-Colonel, and served for some years in Nova Scotia, Bermuda, and Jamaica. In 1834
he retired on half-pay; but in 1837 was recalled into active
service by the Duke of Wellington, and served under
him in Canada, where he proved himself an active and efficient officer. After serving there for more than six
years he returned home, and again retired on half-pay in 1844.
In 1846 he was made Deputy-Lieutenant of the Tower, an office which he held till 1853, when he accepted the
governorship of the Cape of Good Hope, with the command of the forces, and brought the
Kaffir insurrection to a successful termination. On his
return to England he was immediately sent as General of
the Forces to the Crimea, where much was expected from a
man so thoroughly acquainted with the geography of
his profession. He however had short time to display his
capabilities. In the battle of Inkerman, on the 5th of
November 1854, where he displayed the most heroic bravery,
served under him in which he was so perfect a
force so superior that it failed in the desired effect, he fell, to
together with the other leading chiefs. He was buried on the spot
—Cathcart's Hill—by the other officers who had fallen.

CATLINGITE, a form of argillaceous mineral called Pipe-
stone by the North American Indians. It comes from the
Couteau des Prairies, and is a red claystone or compacted clay.
A similar material is now accumulating on the north shore
of Lake Superior, at Nipigon Bay. Another variety is used
by the Indians of the north-west coast of America. (Dans,
Mineralogy).

CATH. MINT. [Naveta, S.]

CATH'S-EYE, a form of Chacodony, of a greenish-grey
colour, having a peculiar opalescence, or glaring internal
refractions, like the eye of a cat, on looking to the
filaments of asbestos. It comes from Ceylon and Malaya,
and possesses considerable value as a gem. (Dans,
Mineralogy).

CATH'S-TAIL GRASS, the common name of Phlim
pennsylvanic, an agricultural plant, also called Timothy Grass.
(Phila.)

CAUCHY, AUGUSTIN LOUIS, mathematician, was
born at Paris, Aug. 31, 1789. His father, Louis Francis
Cauchy, was a poet, and became archivist of the Chamber
of Peers. The son was carefully and religiously educated.
He entered the École Générale in 1804, while at the École Générale
Cathcart, the pupil of the pupil, which had carried off most prizes,
among which was the first in Latin poetry. In the following
year he entered the École Polytechnique as second scholar,

P 2
and in 1806, when only in his seventeenth year, his solution of a difficult problem was printed in the 'Correspondance' of the Academy of Sciences.

From the École Polytechnique, where he rose to the first place, M. Cauchy entered that of the Ponts et Chaussées, maintaining the same position. He was afterwards appointed one of the auditors of the École Polytechnique, and continued this position until his death in 1857, in 1813 he published his 'Méthode pour déterminer les intégrales des équations différentielles' and 'Extraction d'un degré quelconque,' which was followed by papers on the properties of integrals, taking up questions started by Clairaut. In 1816 he received the grand mathematical and physical prize of the Institute for his paper 'Sur le calcul des forces...,' which became the basis of a theory of light.

In 1818 Cauchy was elected a member of the Academy of Sciences, and was appointed professor of mechanics in the École Polytechnique, and in the same year he published his demonstration of Fermat's theorem of the polygonal numbers. His lectures had a most salutary influence on the educational results of the school, and the progress of his pupils was materially aided by the works which he successively published: 'Mémoires sur le Calcul des Finités,' 'Lesons d'Analyse,' 'Mémoires sur le Calcul des Residus à la Solution des Problèmes de Physique Mathématique,' 1827; 'Sur la Réolution d'Equations Numériques, et sur la Théorie de l'Elimination,' 1829; 'Sur la Théorie des nombres,' and others. The last was presented in May 1830. The revolution which followed deprived M. Cauchy of his public employment, as his loyalty to the Bourbon dynasty prevented his taking the oath of allegiance to the government of Louis Philippe. Under this government he was appointed to the office of President of the Bureau of Sardinia, which invited him to deliver a course of physical-mathematical lectures at the university of Ternin. In 1832 the Royal Society of London elected Cauchy one of their thirty foreign members. In the following year he received an invitation from Dr. C. X to undertake the scientific education of the Duc de Bordeaux, which then resided at Prague; and he cheerfully devoted himself to the task. While thus engaged he resumed in 1833 the publication of his 'Mémoires de l'Académie de Marais,' of which he had been for some years interrupted. In 1836 he published his 'Mémoire sur la Dispersion de la Lumière.' In 1838, having terminated his work of instruction, he returned to Paris, and took part in a scheme for training a superior class of public schools. The results of legislation were disappointing, and he was dismissed as a member of the Bureau of the Longitude in 1839, but the minister refused to sanction the choice, remembering the refusal to take the oath of allegiance.

Cauchy's diligence appears to have increased with his years. The number and nature of his communications to the Academy almost bespeak judgment by reference to his 'Comptes Rendus;': at one time they became so multiplied that their publication overstrained the Academy's funds. Concurrently he wrote papers which appeared in other scientific periodicals, chiefly in Louisville's 'Journal de Mathématiques,' among which his 'Notices sur le Développement des Fonctions en Séries ordinaires suivant les Puissances ascendantes des Variables,' published in 1838, is especially remarkable.

In 1840 a professorship of mathematical astronomy having been created at the Faculty of Sciences of Paris, M. Cauchy was appointed to the chair; but, as had happened eighteen years before, his refusal to take the oath required in 1832 to take his public employments. He had continued his studies; adding every month to the number of works. He treated of the higher branches of algebra, the theory of numbers, the infinitesimal calculus, mechanics, astronomy, and physics, exploring indeed every branch of mathematical analysis. The limits of the integral calculus; and if showing a preference for abstract questions, he on the other hand rendered important service to the elementary parts of science, by simplifying the study of asymptotes, introducing the use of limits in the parts of geometry, and by giving an elegant demonstration of the fundamental theorem of the theory of equations.
the Parvis de Temple. On the second day of the insurrec-
tion, Paris was declared a city of siege, and General
(Prussia's) "March in Picardy," all the troops in France
being committed to his charge. After four days' la-
during the contest came to an end by the defeat of the
enemies. The loss on both sides was appalling: two
regiments were killed, four others mortally wounded.
In all, some 8,000 persons were killed and wounded, and
14,000 made prisoners. No sooner had he quelled this
retrograde than the general laid down his authority. The
National Assembly appointed him President of the Coun-
cil, but it was too late. He was there in 1843. The
League, in 1843, was the only covered with a
hundred miles. But he was afterwards allowed to reside
undisturbed in Prague, and it was there that he
published his great work, "The Philosophy of Slavonic
Literature," in 1855. It was at that time the favourite
language of Bohemia, and he then commenced the
study of the Slavonic languages, and made himself master of
them all, as well as of Italian, French, and English, and at
this time made a grand tour of the Slavonic countries.

The most important of the Slavonic countries, says
his biographer Maly, which would be of some interest, but does not appear to have been
printed. His first publication was a volume of "Poems,
which was soon followed by a Bohemian translation of
Herder's "Stella Maris," and a Slavonic translation of
"Feudal Slavonic," says his biographer Maly, which
was the period of transition from the old classic to the
modern style in Bohemian literature, and that the
translation was "the earliest classical specimen of modern
Bohemian prose." A more important production was a collection
of Slavonic national songs, "Slovakie národní písně," in
two volumes (Prague, 1827-28), a publication somewhat
resembling the "Minstrelsy of the Scottish Border." In 1834
Celakowsky purchased a portion of "Lady of the Lake," and
"The Poetical Works of Sir Walter Scott," to assist
in his next translation, the "Choral písni Rusky," a
collection of Russian national songs, so beautifully rendered
into the kindred Bohemian that they at once took a very
high place in the literature of that country, and still retain it.

Bohemian was at that time the favourite language of Cela-
kovsky, and the Russian nation was high in his esteem, so
much so that he lost the friendship of several of his Bohe-
man acquaintances on the outbreak of the Polish insurrec-
tion in 1831, from taking the part of the Russians against
the Poles. He had then been for some time the editor of
the leading Bohemian newspaper at Prague, a post to which
he had been recommended by his patron, Count Chotok, and
he was also professor of the Bohemian language at the
university. When the Polish insurrection was suppressed how-
ever, he disapproved of the severity of the measures adopted
by the Emperor Nicholas, and in an article of his paper
condemned the proceedings of the Czar to the tyranny of the
fatherland of the Golden Horde over conquered Russia, in
which happened to pass the censorship, but did not elude
the vigilance of the Russian embassies at Vienna; a complaint
was made to the Austrian government, and the unfortunate
author was dismissed from his establishment and his
profes-
sorship—or in other words, he was ruined. A paradox of
bitterness Celakowsky composed a volume of epigrams
against his persecutors, but as might be expected, the per-
sons to print them was refused. He obtained the place
of librarian to the Princess Kinisky, and published some
poems of a milder character, of which the "Hundred-Leafed
Rose" ("Roz Stobieta") is spoken of as the finest. His fame
was at this time widely extended. Dr. Bowring, now Sir
Cornelius, dedicated the second edition of his "History of
Anxiety," in some stanzas in which he spoke of the kind-
ness Celakowsky had shown him on his visit to Bohemia,
and the material assistance he had afforded him in the
pre-
paration of the volume. The present King of Prussia was
soon after his accession induced, by a deputation, to pro-
found professorships of Slavonic literature at two of his uni-
versities, Berlin and Breslau, and Celakowsky was offered
the choice of either. He selected Breslau, and removed there
in 1843. He enjoyed his second competence, but in what
appeared to him a exile, in a country which had ceased to be
Slavonian. He was always eager to grant any Slavonians
who came to Breslau, and the time of vacation always found
him at Prague. At length the events of 1846, so disastrous
for the liberal mass of Slavonic democrats, brought to the
capital led to its bombardment by Windischgrätz, brought
about Celakowsky's return to his native country.
In the following year a Professorship of Slavonic Philology
was instituted at Prague as a concession to the national party,
and it was offered to Celakowsky, whose offers were pro-
bably considered as sufficiently expiated by his seven years'
expatriation. He returned, but his friends perceived that he
was no longer to remain among them. Always of a somewhat
optimistic taste and in a way wild and passionate, he
found himself in a domestic calamity, particularly the loss of his
wife, who left him burdened with a large family of children, had shaken his
mind. He died on the 6th of August 1853.

Some of Celakowsky's works have been already men-
tioned. The most important of his publications is his
"Mudrošivá různice slovenšćeho v pravičći" ("The
Philosophy of the Slavonic nation in prose"), a valuable
collection of that nature, attracting much attention on its
appearance after the era of 1848, and so much increasing
his hitherto large manuscript collections, which are likely to be
the light under the editorship of a friend. He had also
been for years engaged in collations for a supplement to the
valuable Boho-mian dictionary of Jungmann, and on an
other occasion was a contributor to the Czech and Slavo-
nic dictionaries, as in the great Polish dictionary of
Linde. This work is also desired for publication, and, it is antici-
pated, will prove a contribution to Slavonic literature of the
very highest value.

CELANO, the ancient Freccia, a lake in the Abruzzi
in Italy. It is remarkable as being almost exactly in the centre
of the Italian peninsula and the only lake of any consider-
able extent in the Central Apennines. The lake is nearly
in a right angle in shape, about 4 miles in breadth and
about 2176 miles long, and surrounded on its west by
the Garigliano, a large, long, and narrow stream, and
its surplus waters were carried off by subterranean
channels, the opening of one of which is still visible, and called La Pedogna, a name clearly
derived from Plutarch. The lake, however, was too insufficient, the lake frequently overflowed the low-lying
areas along its banks. To obviate the evil, Julius Cesar designed to cut a tunnel from the lake into the valley of the Liris; his plan, however, was not carried into effect till the reign of Claudius, who celebrated the opening of the tunnel with great magnificence.

In the middle ages the tunnel became obstructed by the
falling in of stones and earth, and many attempts have been
made since the year 1540 to render it efficient in preventing
inundations of the lake, but without success. Between 1745 and 1850 the encroachments on the lake had swallowed up about
20% of its area, and in 1870 the system of embankments and repairs, however, were made at the expense of the King of the
Two Sicilies, under the direction of Signor de Rivara (who examined the tunnel in detail, and described it in 1852), and the ancient
lake was considerably restored as to carry off a constant, though not a large, stream of water into the
Liris, or Garigliano. The area covered by the lake, according to a late official survey, is 36,315 acres. A company
was formed at Naples in September 1862 to effect the
complete drainage of the lake.

Considered as a remnant of antiquity, the tunnel of
Claudius is an exceedingly interesting object. At the opening of it, near the lake, the tunnel is about 80 feet high and broad, and then it contracts gradually as it advances through the mountain. Its whole length is three miles. It is in part cut through the solid limestone of Monte Salviano, and in part through a chalky earth that has little tenacity. At the further end the lower substances occurs, the tunnel is supported by machinery of admirable workmanship. To admit light and air the Romans sank shafts from above. The entrance to this tunnel is about a mile and a half to the south of the town of Avezzano, on the north-west shore of the lake.

CEI.BRIDGE. [Kidman.]

CELLS. The ultimate structure of animal and vegetable bodies consists of minute vehicles, which are called Cells. In both animal and vegetable structures these organs are not generally visible. The muscle derived from a 1-600th to the 1-1000th part of an inch in diameter. In all cases they consist of an enveloping membrane or cell-wall, which incloses in a space more or less enlarged certain constituents, called cell-contents. The nature of the substances which enter into the composition of the cell-walls and constitute the cell-contents, differs in the animal and vegetable kingdoms, but there are certain properties which all cells possess in common. Sometimes these properties are essential to the cells, and in other cases, it appears they are possessed by inorganic or mineral bodies, which are called cellular. It will, however, be seen, that, independent of the formative power by which particles of gelatine, cellulose, &c., arrange themselves in the form of cells, and again these cells arrange themselves into the form of organs; and further, that the formation of a cell is, in some form, there are few of the functions performed by cells that may not be referred to the action of physical forces. One of the first and most necessary conditions of the cell is, that it shall allow of the passage, through the membrane of which its walls are composed, of those substances by means of which it grows, and which it acts upon for the production of the peculiar secretions which characterise either specific beings or parts of their organisation. This function, which is of the greatest importance to the practical relations of life, which exist between liquids and gases and the membrane of which the cell-wall is composed. [Assimilation.]

The liquid or gaseous contents which are thus introduced into the interior of cells undergo a variety of changes, according to the position, age, or other circumstances of the cell. Sometimes the fluid that is absorbed appears to be transmitted in compound structures from cell to cell without undergoing any great amount of change. In other cases, the materials thus taken in are converted into new substances. The cells of some parts of vegetable structures are an instance of the latter, in which carbonic acid and ammonium are absorbed with water, and converted, either during their passage through the cell-wall, or whilst in the interior of the cell, into carbonic acid, of the gas, organic matters forming part of the cell. In other parts of plants the cells convey solutions of sugars and other substances without producing on them any change.

The constituents absorbed into the interior of the cell are the materials from which the cell-wall and all its contents are derived. The process by which the cell appropriates to itself these matters is called Assimilation. This function is supposed to be carried on by an independent force or power residing in the cell, or organies of cells, which form an organ or a body, and has been called the assimilative force or property, 'organising force,' 'plastic force.' It is necessary however in this process to separate between the changes by which one substance is converted into another, and the changes which arise solely from the use of ordinary chemical forces under other circumstances, and the power or force by which these substances are made to assume definite forms in cells and organs. The latter is a special force in the case of each cell, plant, or animal, and to which alone, of the changes involved in the function of assimilation, the term vital can be properly applied.

The result of the appropriation of the new matter absorbed from without in all cells is their enlargement or growth. The manner in which this takes place is either the new matter taken up into the interior of the substance of the cell-wall, which is always the case where the cell becomes augmented in size, or it is deposited in the form of layers in the interior walls. According as the first mode of growth is regular or irregular will be the form of the cell. The vegetable and animal kingdoms present almost all conceivable forms of cells, from the spherical and hexagonal cells observed in the vegetable kingdom, and the less organised tissues of animals, as cartilage, up to the elongated vessels of the plant, and the irregular cells of bone and areolar tissue in animals.

The animal kingdom presents by far the greatest variety in this respect, and so great are the changes that some of the animal cells under the term cellular metamorphoses of transformations have been applied to these changes. As examples of these cells we may quote—the hoarse scales of the epidermis, of the hair and the nails, and the laminated pavement, epithelium—in which the cells are flat, the nuclei are displaced, and the cell-wall is fused into one mass with the cell-contents; the contractile fibres-cells of the smooth muscles; the tubules of the lens; the prisms of the enamel; the various forms of bone-cells; and the transversely striated muscular fibres.

All cell-origins are or produced in the same way. Either they are developed free in vegetable or animal fluids, or they are produced in the interior of preceding cells. In all cases they originate in connection with a substance called protoplasm, which exists in cells, either in the form of a small dark spot called a nucleus, or cytoplasm, in the interior of which is a nucleolus, or of an expansion on the interior of the cell, when it is called the primordial utricle. Free cell-development has been observed to take place in plants, in a vessel of sap, and in the sap of the paramecium. Absorption—certain, and amongst animals in the chyle, blood, and lymph. The exact mode of the development of cells under these circumstances has not been accurately observed; and the particles or granules of protoplasm, which separate from or are yet been proved to have had their origin independent of other cells. The most common form of cell-development is that in which the cell grows around or from the nucleus or primordial utricle. In the case of a cell surrounded by a mass, it is said to take place around the nucleus, whilst in the vegetable kingdom its origin is more frequent from the folding in or contraction of the primordial utricle upon itself, by which means two cells originate in one.

One of the highest problems for the physiology of the present day to solve is, the efficient causes of the phenomena of cell-development. The following propositions have been laid down by Külliker as an attempt to follow up Schwann's principal solutions, and which demonstrate the changes in inorganic bodies and those which occur in cells:

1. The nucleus of the cell arises in the first place as a precipitate in an organisable fluid, and afterwards becomes consolidated in such a manner that a special investment and contents with a nucleolus appear. Its development may in this case be compared to that of inorganic precipitates, yet the constantly globular figure and size of the nuclei which are just formed, indicate some essential though not yet recognised condition peculiar to them.

2. In the development of cells by division the cell-nucleus plays exactly the same part which was previously ascribed to the nucleolus, and the occurrence of the formation of cells in this manner demonstrates that chemical conditions are not necessary in the development of cell-sides.

3. In cell-development around portions of contents, and in the cleavage-process, the nuclei also operate as simple centres of attraction on a certain mass of blastema, and then follows the formation of a membrane upon the surface of this mass. This is most simply understood as a condensation of the blastema.

4. In the cell-development directly around the nucleus the investment with blastema is wanting, and the nucleus deceased in the interior of the cell.

From what has been previously said, it will be seen that the cells are the active seat of the functions of both animals and plants, and the most conspicuous results of organisation take place in consequence of their agency. They not only constitute the mass of the body, but by their agency the special secretions and products of individual plants and
animals are formed. The food is conveyed into the body by cells, the blood of animals is charged with cells, and the essential functions accompany the agency of cells. Nor are these last functions peculiar to the animal kingdom. Contrastibility and sensibility seem to be the property of the substance (protein) of which the nucleus and prismatic unit cells are composed. To this substance Mr. Dana, however, subscribes a much greater significance, and includes a lecture on the identity of structure of plants and animals:

In b-th plants and animals there is one histochemical character and structure. If the formative organ be divided in a vegetative way, the new substance (the cell membrane) being the subject of all the chemic and morphological metamorphoses, in consequence of which specific tissues arise. The differences between the cells of the endoderm and the mesoderm, in plant and animal life, and, as the prismatic unit, attains a large comparative size; while in the animal the Endoderm remains small, the principal bulk of its tissues being formed by the prismatic substance; and, 2, in the nature of the chemical changes which take place in the prismatic substance in each case.

This distinction however does not always hold good, the Asidnus furnishing examples of animals whose prismatic substance contain cellulose. Each cell, each plant, is inclosed in a wooden case and nature, like Sycorax, holds thousands of 'delicate Areals' imprisoned within each oak. She is jealous of letting us know this; and among the higher and more conspicuous forms of plants reveals it only by such obscure manifestations that they are required to counterfeit the Bus, to imitate the Drosophila, or, still more slightly, by the phenomena of the Quedia.

But among the immense variety of creatures which belong to the invisible world she allows more liberty to her Dryadse; and the Protocerci, the Velumis, and indeed all the Arthropoda, are during one period of their existence as active as animals of a like grade in the scale. Then, they are doomed eventually to shut themselves up within their wooden cases and remain quiescent; but in this respect they are no worse off than the Lepidoptera and other insects of a like state.

For further information on the subject of Cells, see the articles Histozy, S.B. ; Cell, S.J. ; Tissue, Organs, S.1. (Sharp, in Quain's Elements of Anatomy; Kölliker, Handbook of Human Histology, translated for the Sydenham Society by Huxley and Braek; Carpenter, Manual of Human Physiology; Principles of Physiology: Mohl, On the Vegetable Cell, translated by H.N.; Schleiden, Principles of Scientific Botany, translated by Lkenster; Schleiden, On Phytogenies; Sehman, On the Identity of Structure in Animal and Vegetable Kingdoms, translated for the Sydenham Society; Quack; Lectures on Histology; Hambl, Microscopic Anatomy of the Human Body; Todd and Bown, The Physiological Anatomy and Physiology of Men; Quack, Cautions and Observations in 1851, Wood's Medical College of Surgery, London; Quarterly Journal of Microscopic Science; and Transactions of Microscopic Society, vol. 1.)

CENSUS OF 1851. The Census of Great Britain in 1851 differed in several respects from any previous Census. In some points the range of its inquiries was more minute and precise; in many others wider and more comprehensive. The character of the previous inquiries and the extent to which they reach out have been sufficiently indicated in former volumes of the Penny Cyclopædia. Here, therefore, without giving some of the principal results of the Census, it will be enough to state, in the words of the very elaborate Report of the Registrar-General, prefixed to the volumes of Population Tables, printed by order of Parliament, what the Census of 1851 was about to achieve:

"At the present Census it was resolved to exhibit not merely the statistics, as before, of parishes, and, more completely, of parliamentary and municipal boroughs, but also of many other large towns in England and Scotland as appointed sufficiently important for separate mention, and of all the ecclesiastical districts and new ecclesiastical parishes which, under the provisions of various Acts of Parliament have, during the last forty years, been created in England and Scotland. In addition to the information of occupation, age, and birthplace, of the population, it was determined to ascertain the various relationships (such as husband, wife, son, daughter)—the civil condition (as married, unmarried, widower, or widow)—and the number of persons blind, or deaf and dumb. Further, under the impression that the fifth section of the Act would authorise such an inquiry, the design was formed of collecting statistics as to the amount and distribution of the population in the ten preceding years; the general system of registration of births, deaths, and marriages, which had been for that period in full operation, affording more complete and trustworthy information than that which could be obtained from the population returns of the previous Census."
enumeration books, and other forms, despatched from the central office, exceeded 25 tons. The schedules, after being dispatched to the enumerating officers and superintendent-registers before transmission to the Census Office, there to undergo final revision and generalization. The enumeration of the persons on board vessels, vessels in the navy, and vessels of the Customs, the Admiralty, and the Register of British Seamen; the enumeration of the army by the officers of the various branches, under the direction of the Commander-in-Chief. In these, as in other matters, the returns were much more complete than in the preceding Census, while several collateral returns were at the same time obtained, such as of the latest population of the several colonies, the number of British subjects in various foreign states, the number and rank of half-pay officers of the army, navy, and merchant service of Great Britain and Ireland, officer of the armed service, employed in the civil service of the Crown, &c.

We proceed now to the results of the enumeration of the population. The number of people in Great Britain, including the islands in the British seas, on March 31, 1851, was 20,859,477; and the men in the army, navy, and East India Company's service, abroad, on the passage out, or round the coasts, belonging to Great Britain, on the same day, was 162,490. The total population of Great Britain may therefore be estimated at 20,328,467. Out of England, 1,005,721 in Wales, 2,665,742 in Scotland, 143,126 in the Isle of M., Jersey, Guernsey, Alderney, and other small islands in the British seas; and 162,490 were at sea.

The proportion of males to females has been preserved with remarkable regularity during the half century. In 1801 the male population of Great Britain was 10,386,048, the female 9,940,419; in 1811, 10,386,048 males and 9,940,419 females; in 1821, 10,365,929 males and 9,918,300 females; in 1831, 10,365,929 females to every 100,000 males; in 1841 it was 103,353 females to 100,000 males. At both periods there were somewhat less than 30 males to 31 females. In 1851 there were 20 males at home to 31 females. The excess of births, however, is in the opposite direction. During the three years (1850-51) in which accurate registers of births have been kept, there have been born 3,534,232 males and 3,463,299 females, or about 105 males to every 100 females (104,840 to 100,000). The disparity in the sexes at home is greatest in Scotland—110 females to 100 males; in England and Wales it is only 104 females to 100 males. To what degree the change in the proportions and the subsequent disparity of the numbers in the two sexes is due to emigration, or to a difference in the rate of death from disease and disease to which they are respectively exposed, is the question to consider.

The increase of population in the last half-century nearly reaches the new action equal to that which existed in Great Britain at its commencement, and that notwithstanding the vast numbers who have "annually left the United Kingdom, settled and multiplied in millions in the United States, in the colonies of North America, of Australia, and of South Africa." The aggregate increase in the fifty years is 89,470 per cent., or at the rate of 1,399 per cent. annually. "The annual increase, however, has varied in each decennial period; it increased from 1,374 per cent. on the population in 1801-11, to 1,489 (nearly 12 per cent.) in 1811-21, when it was at its maximum; the annual rate of increase in 1821-31 was 1,406; in 1831-41 it fell to 1,379; and in 1841-51 to 1,186 per cent. annually. The population therefore increases, but the rate of increase has declined since 1811-21, when there was least immigration and most mortality. The rate of increase is still more than it has ever been before or since, down to the last two last decades; when the public health has suffered from epidemics of influenza, cholera, and other diseases; while emigration from the United States has been at an accelerated rate from 974,300 in 1821-31, to 1,098,000 in 1841-51." During the same period the proportion of land to each person has decreased in Great Britain from 9 acres in 1801, to 7 acres in 1841; from 4 acres in the United States and West Indies.

If the rate in which the population has increased since 1801 continued to prevail uniformly, the population would double itself in Great Britain every 62 years; in England and Wales every 51 years.

The number of families in Great Britain in 1801 was 2,960,602; in 1851 it was 4,312,588; being an increase of 2,351,986. The families in England and Wales in 1801 were 1,866,735; in 1851 they were 3,713,990. In Scotland they were 3,044,078 in 1801, and 3,837,151 in 1851. The average number of families to a house in Great Britain in 1801 was 1.209; and of persons in a family, 4.645; in 1851 there were 1.182 families to a house, and 4.582 persons in a family. In Scotland in 1801 the average of persons in a family was 4.614; in 1851, 4.572; and in the Channel Islands, 1.600. The average number of families in a house was somewhat higher—1.621. In Glasgow the number of families to a house is 5.4; of persons to a house, 27.5; in Edinburgh the corresponding numbers are 4.2 and 20.6; in Aberdeen, 3.2 and 20.2; in Dundee, 2.2 and 17.6; in Perth, 2.6 and 12. In London, on the other hand, the number are only about the average of Scotland—1.74 and 7.7; but in some districts they are as high as 10, 11, and even 15 persons to a house. This excess in the northern cities was caused by a real difference in the habits of the people. "The towns and cities of the two northern English counties and of Scotland are built in the continental style; and the families of the middle classes, as well as the poor, live in large flats, which constitute separate tenements. The term house, in many parts of Scotland, has been usually applied to these several flats or floors; and in every census from 1801 to 1841 'flats' in Glasgow and some other Scottish towns were returned as separate houses. In 1851 this was corrected, and the enumerators were instructed that flats and similar buildings were to be returned as houses. The returns from Scotland, as from England, are now, therefore, made on a tolerably uniform principle, and are fairly available for comparison. The variations in the several English counties and in different districts with respect to the proportion of families to houses, is considerable; but it would require far more space than we can spare to enter upon it. As a rule, in England and Wales, a house is inhabited by one family, the excess in the proportion being mainly caused by the large number of public institutions, such as lodging-houses, &c. The following is an analysis of the families in connexion with the houses which they occupy in 14 subdistricts of England, containing 35,876 inhabited houses, in which were 38,968 families (1,600 of the houses having the families absent), comprising 242,164 persons, on an average, nearly 7 persons to a house—5 to a family. Of these houses, 36,300 contained one family; 4,789, two families; 1,023, three; 745, four; 432, five; 252, six; 113, seven; 62, eight; 38, nine; and 30, ten families and upwards. This analysis is in the Report carried out with great minuteness into a variety of particularities, but which it is impossible for us here to follow. The number of houses in Great Britain in 1851 was—inahebitated, 3,670,193; unoccupied, 166,725; building, 29,104. In 1801 there were 1,828,476 inhabited, and 67,320 uninhabited; the number building was not returned. The following tables (1) the number of principal parish institutions, of those inns which 30,316 were officers and servants; and (2) the number of persons sleeping in barges, barns, tents, and vessels.
in one instance that a tribe of gipsies struck their tents and
paused into another parish in order to escape enumeration.
In 1841 the number of the houseless class was 52,303 : owing
to the more advanced period of the year (June 7) at which
the Census was taken, and the absence of many Irish people and labouers
were then engaged in the hay harvest."

From houses and families we ascend to towns and corpora-
tions.
No attempt was made to classify the smaller aggre-
gates of houses by defining villages, hamlets, &c.; but 17,150
places were named as towns in the Great Britain
in the Population Tables, and each of these is assumed to
be a village, or an aggregation of families round a church or
chapel; on an average these villages lie at a distance of
about 8 miles apart, so that the inhabitants of the country
average 32 persons to the square mile; and the average limit of 1 mile from the centre, or at the mean
distance of six-sevenths of a mile.

"Great Britain has eighty and fifteen towns of various
magnitudes, 13,006, or Great towns, containing
a city, five hundred and eighty in England and Wales; two
hundred and twenty-five in Scotland, and ten in the Channel
Islands. To 21 of the preceding 'villages' there is on
an average a town, which stands in the midst of 110 square
miles of country, containing a hundred and sixty persons by
side, a circle having a radius of nearly 6 miles; so that
the population of the country around is, on an average, 4
miles from the centre.

The population amounted to 10,586,888 in the 815
towns containing 3,184 miles of area. An average
town of 19,933 inhabitants stands on an area of nearly 4
square miles; equivalent to a square of 3 miles to the side,
a circle 1.5 miles to a radian, and the population is less than
three-quarters of a mile from the centre.

The average area of the towns of Great Britain was
10,430,189; consequently if, for the sake of distinction, the
detached houses, the villages, and small towns without
markets, are called—country; at the present time the town
classification of Great Britain differs little from the
numbers, that they may be considered equal, for by the
abstracts 10,566,888 people live in the towns, and 10,430,189
in the country. In the towns there were 32 persons to as
acre, in the country 63 acres to a person. The density in the
country was therefore a smaller one, in the towns 3,527 persons—
to a square mile.

The 815 towns are grouped around 87 county
towns—Edinburgh, London, in England and Scotland, and 3 chief towns, equivalent
to county towns, in the Islands of the British Seas. Each of
these towns is a capital of some county, and may be
considered the port of trade for a hundred miles on
the whole, and is generally the residence of a great
manufacturing city.

The equality of proportion between the town and country
population of Great Britain is one of the 'great facts',
which brought into prominent notice by the Census of 1851.
The great relative increase of the population collected in
the principal towns is another of the most important facts which
point to a change in the habits and condition of the people.

Thus, in the 61 principal towns in the England and Wales,
which in 1801 contained 2,133,388 inhabitants, the
population had risen in 1851 to 6,594,521; in other words, in
England and Wales the population of Great Britain included
those 61 towns, while in 1851 very nearly 35 per cent.
of the population resided in the same towns. In the seven
principal towns in Scotland there resided in 1801, 571,490
of the entire population of Great Britain, while in 1851,
776,696 out of the entire population of 2,888,742,
or 26.9 per cent.; or there occurred a relative increase in
the 68 largest towns in Great Britain of upwards of 10 per cent.,
as compared with the increase of the entire population; that
is, in the proportion of 68 out of the 61 towns in Great Britain
resided in 68 of the principal towns, now three out of every
ten persons reside in them. The increase of the population
of London and the other great towns was 4,609,332, or 189
per cent. in the half-century; that of the smaller towns and
villages was 387, or 17.5 per cent. The actual increase in some of the great towns was very remark-

able. In London the population increased from 956,883 to
3,269,826, being an increase of 1,403,973, or 146 per cent.;
Manchester (with Salford) from 947,786 to 401,336; Liverpool
from 83,959 to 375,585, its opposite neighbour Birken-
head rising in the same time from 110 to 24,386; Bir-
kirk from 27,070 to 94,941; Preston from 16,174 to
96,848; Bradford from 13,764 to 107,778; Plymouth
from 16,040 to 32,821; Southampton from 7,913 to
35,305; Merthyr-Tydyl from 10,127 to 63,080; Glasgow from
77,038 to 328,007; and other manufacturing, mining, and sea-port
towns, the increase of inhabitants in the population of the waterings-places, or towns chiefly devoted to trade,
meanwhile being at least commensurate with that of the towns devoted to business: thus Brighton increased from
7,440 in 1801 to 69,673 in 1851; and Cheltenham from
12,776 to 35,361 in the same period.

Dividing the towns into classes, it appears that "the
greatest part (3,029,776) of the increase (5,363,650) of
the classes of towns was in London and in the manufacturing
towns; the (1) sea-ports, the (2) towns which are in mining
districts, or are engaged in hardware manufactures, and the
(3) county towns, severally contributed more than three-
quaters of a million to the increase; the increase of the people living in watering-places was 200,164. In the latter
class the greatest was the rise in the Channel towns; it was 3.961 per cent. annually. The annual rate of increase
in the manufacturing towns, 3.336 in the mining and hardware
towns, 2.191 in the sea-ports, 1.890 in London, and 1.809 in the county towns. The annual rate of increase in Great
Britain in the half-century was 2.677. The towns have increased most rapidly in which straw-plait, cotton,
pottery, and iron are manufactured.

The density and proximity of the population are elucidated
in the Report and the Summary Tables in various ways, and
may be considered at this stage as sufficiently treated
briefly. The density of population, or, as a recent French authority (Baron de Prony in the 'Annaire') has
proposed to term it, 'the specific population,' after the
methodology of 'Prony,' is given for the 964 districts of
England and Wales, from 155,761 persons per square mile
in the East London district, to 18 on a square mile in
that of Bellingham, Northumberland. The greatest density
of population out of London is in the Liverpool district,
which is 74,446, and the next Birmingham, which is 41,853
on a square mile. Manchester has 11,577, which is less than
Leeds, which has 30,886; Bristol, which has 22,586; Plymouth,
which has 30,441; Nottingham, which has 19,094;
East Stonehouse, which has 10,913; Brighton, which has
19,085; Hail, which has 17,750; Salisbury, which has
11,907; Greenwich, which has 11,849; and Exeter, which
has 11,670. The smaller density of Manchester than such
towns as Salisbury and Exeter is accounted for, in a great
measure, by the large spaces covered by the numerous
great factories and workshops; and any great town, whose
spread would be generally expected, especially as both Exeter
and Salisbury are cathedral towns, having considerable open
spaces within the city boundaries. But the evidence of
over-crowding in those cases is diminished by the fact
that they are compared with some of the other most populous
manufacturing towns: Sheffield, for instance, which is among
the densest, has 6,863, or little more than half as many on
the square mile as Salisbury; Bradford, which has 2,887,
or less than one-fourth; and Blackburn, which has 1,393,
or only one eighth. As respects proximity of population,
regarding it upon the same hypothesis of equal distribution,
we find that the people of England were, in 1801, on an
average 153 yards a seader, while in 1851 they were only
108 yards a seader, which is a great advance. In 1801 there
were 628,262 yards, and 292 yards in 1851. Or, as it
may be otherwise expressed, on the same area the population
has doubled; the proximity has increased—the separation
less than a fifth part of 3.849 per cent.; but of course
the mean proximity has increased from 21 yards in 1801
to 14 yards in 1851.

The Islands of the British Seas are noticed more fully in
this than any previous Census. Five hundred islands and
rocks have been enumerated by the census takers; these were
found on the morning of March 31st, 1851 on 175 islands, or
groups of islands. Some of the others are, however,
ocassionally dwelt on by shepherds during summer. Passing
grey Ireland, the Census of Great Britain has been defended to
that four of the larger islands or groups of wards of 50,000
inhabitants—Anglesey 67,318, Jersey 57,020, Isle of Man
89,344, Isle of Wight 60,264. Four others have each above
20,000 — Guernsey 29,757, Lewis 28,918, Skye 31,589, and Shetland 20,936. Two more number upwards of 10,000 — Orkney 16,665, and Islay 12,534. Twenty number between 1,000 and 10,000 inhabitants; fifteen between 500 and 1,000; thirty-seven between 100 and 500; fifteen between 50 and 100; forty-five between 10 and 50; seven number 10 inhabitants on each; and twenty-five under 10, two of whom having only one inhabitant on each, Little Papa, one of the Shetlands, a woman, and Inchcolm, in Fife, a man. Some of the more remote and smaller islands were now numbered for the first time, and much curious information has been collected. St. Kilda, one of the Hebrides, 70 miles from the mainland, is one of these. The population, now for the first time officially enumerated, consisted of 48 males and 69 females, of whom 25 were on board a vessel, and the remainder, except one female, aged 35, who was imported from Sutherlandshire. The excess of females is chiefly among children under 20, of which there are 32 males and 30 females; and persons above 60, of whom 6 are females and 1 only is a male. The men are all farmers and bird-catchers, each "farmer" occupying about three acres of land. Eight females are described as "weavers in wool." The great majority of children die of what is called the "eight days' illness;" several were born during the previous twelve months, but only two were living. There are a manse and a church on the island; but no resident clergyman or medical man.

The number of boroughs in England and Wales having municipal organisation according to the Municipal Reform Act, was 186, with a population of 4,348,369; of the remoter boroughs 18 have had charters of incorporation granted since the passing of that Act. There are 89 unreformed boroughs. Of the reformed boroughs it is found that one-half of the population (2,293,542) is contained in 17 boroughs, each of which contains more than 60,000 inhabitants. It appears that 102 boroughs, or more than half of the total number, contain less than 9,000 inhabitants in each; in the aggregate, 472,610 inhabitants. Eighty-seven boroughs have from 2,000 to 7,000 inhabitants; twenty-seven, from 500 to 40,000; one, from 40,000 to 60,000; seven, from 60,000 to 80,000; two, from 80,000 to 100,000; and three have 200,000 and upwards.

The 83 royal and municipal boroughs of Scotland contained 775,777 inhabitants; only three boroughs contained more than 60,000 inhabitants; one, more than 40,000; three, from 20,000 to 40,000; fifteen, from 7,000 to 20,000; thirty-three, from 2,000 to 7,000; and twenty-eight under 2,000 inhabitants.

Several of the most populous and important places in England and Wales are still without a municipal organisation. Among these are the metropolitan parliamentary boroughs of the Tower Hamlets, population 639,111; Finchley, 325,729; Marylebone, 370,597; Greenwich, 103,764; Lambeth, 231,349; and Westminster, 241,611, and the towns of Brighton, population, 69,673; Burton, 30,626; Bury, 31,262; Chatham, 28,424; Cheltenham, 35,061; Dudley, 37,960; Huddersfield, 30,800; Merton, 32,863; Rochdale, 29,196; Stirling, 36,595; and Stoke-upon-Trent, 84,027.

In Scotland there are no towns containing a population of 10,000 which are not municipal boroughs. Additional abstracts, of a very valuable character, have been published subsequently to the General Report relating "to the ages, occupation, civil condition, and birth-places of the population; the numbers of the blind, and of the deaf and dumb; and the extent of the accommodation throughout the country for the purposes of education and religion;" but this is not the place to go into questions of so wide a nature. In another article will be found a notice of the Occupations of town Populs [2. 2] as exhibited in the Census returns.

With respect to Ireland, the circumstances brought out with most startling prominence was the remarkable decrease in the population since the previous Census. Up to that of 1841, each decennial Census of the half-century had shown a steady if not rapid increase of the population. That of 1851 showed that during the past ten years the gain of the previous twenty had been more than undone. In 1841 the total population of Ireland was 6,501,897; in 1851 it was only 6,551,970. And the returns further showed that this decrease was greatest in the rural districts. The population of towns, as compared with 1841, the only exceptions were some two or three places in Ulster, in each of which, from causes easily understood, there had been a continuous increase of inhabitants during the half century. The large falling off of the population between 1841 and 1851 was mainly owing to the disasters famine which afflicted Ireland in 1845-47, in consequence of the failure of the potato crop; partly, however, it was due to emigration, which, in its turn, had been greatly stimulated by the failure of the potato, and the consequent agricultural distress. The total emigration from Ireland during the ten years between 1841 and 1851 is estimated to have amounted to 1,589,138, "varying with considerable regularity according to the variations in the state of the labouring classes." For the return showing in one view the increase and decrease of the population of Ireland, we append a table of the number of inhabitants in the four provinces at each decennial Census from 1821 to 1851.

The reduction of population was as might be expected most marked in the rural districts. In several of the large towns the Census of 1851 showed an actual increase of population, while scarce any showed a falling off, a circumstance arising no doubt from the farming poor having crowded into them in the hope of obtaining employment or of finding relief. Dublin city, which in 1851 contained 165,681 inhabitants, had 252,726 in 1841, and 253,971 in 1851. Certainly, though it showed a decline of nearly 16,000 between 1821 and 1831, and an increase of above a thousand from 1841. Belfast had more than doubled in population between 1821 and 1841, and between 1841 and 1851 had increased from 76,308 to 100,300. Galway town, which between 1831 and 1841 and 1851 had fallen in population from 33,190 to 17,257 had increased in 1851 to 23,696.

The two following tables will show in the readiest manner the general results of the enumeration of 1851.

In the article Great Britain of the 'Penny Cyclopedia' a table is given of the population of the counties of England, Wales, and Scotland, with the areas in square miles, according to the Census of 1861, and under the head Ireland a similar table is given for that island. In the former Supplement, under the head Counties, are given the population of the counties of Great Britain and Ireland, according to the Census of 1841. We now give tables of the population of Great Britain and Ireland, with the areas in acres, according to the Census of 1851, followed by a list of towns in Great Britain and Ireland, arranged under their respective counties, with the population of each in 1851.

the towns generally contain a popu
lation of 2000 and upwards, but several are also inserted
which have a smaller population. The Parliamentary Boroughs are placed first ; then follows the list of the towns,
including the parliamentary boroughs, which are in many
instances also Municipal Boroughs, having*a population
The
different from that of the Parliamentary Boroughs.
Burghs and Contributory Burghs of Scotland are arranged
under their respective counties, but a list of the Parliamentary Districts of Burghs is given at the end of the list
for Scotland.
The abbreviation P.B. signifies Parliamentary Borough ;
C. P. B., Contributory Parliamentary Borough ; M. B., Municipal Borough, and includes the Scotch Royal Burghs.
Sometimes p. and t. are inserted in the figure-column, and
signify Parish and Township, where the returns of the
census do not state the population of the town itself.

</table>
however a very different thing from the true Beldillum. 

CEDRO, a genus of plants belonging to the natural order Cunoniifera. It is characterised by its sepals being very numerous, imbricate, adnate to the base of the ovum, united into an elongated tube, one outer shorter and like a calyx, middle ones longer and coloured, innermost ones petaloid; the style thickened at the apex; the berry annual, the fruit a fusiform capsule. The species are feby pinnate shrubs, with a woody axis and soft interior. They possess angles which are vertical and covered with teeth of spines. The flowers are large, arising from the angles of the fronds, white or yellowish, petaloid, the sepals ovate. C. emilia, the Old Man Torre-Thistle, is an erect plant, bearing a stem with 20-25 vertical ribs, covered with fascicles of bristles, each fascicle containing from 15-20 radiating armed curved bristles. Its long gray bristles give it the appearance of the head of an old gray-haired man. It is a native of Mexico. C. flagellaris, the Creeping Cereus, has prostrate stems with about 10 angles. It is very common in our gardens, and its trailing stems furnish support of trellis-work. It is a native of South America, though now naturalized in Asia and Africa. C. grandiflorus, the Night-Flowering Cereus, has rooting stems, 5 or 6 angles and fascicles, with bristles in each fascicle. It is a native of the West India Islands, and is found in many parts of the mainland of South America. This plant when cultivated produces very large beautiful sweet-scented flowers. They are however of short duration. The plant was called the "beauty of the West," and the flowers were used for perfume. He was of opinion too, that by devoting a day or two each week to the preparation of his sermons and to official clerical acts, a clergyman could amply discharge all his proper duties, so as to have the rest of his time at his disposal for whatever other occupations interested him. He carried this view into practice. During the first year of his incumbency he varied his professional work at Kilmany by courses of lectures on mathematics and chemistry at St. Andrews. His reference to the physicist, and for natural science over theology was indicated by his being candidate in 1804 for the chair of Natural Philosophy at St. Andrews. With even less success of advantage he offered himself in the following year as a candidate for the mathematical chair at the University of St. Andrews. Mr. Leslie, afterwards Sir John Leslie, obtained the post, and it was with reference to an argument in Leslie's favour urged at the time by Playfair, to the effect that "the vigorous prosecution of mathematical or natural science was incompatible with clerical duties and habita" that Mr. Chalmers made his first literary appearance. In reply to Playfair he published an anonymous pamphlet, vehemently defending the clergy against what he regarded as a "separatist and unnatural speculation"—a pamphlet, the main tenor of which, if not its specific statements, he lived to disown. His next publication was in 1807, when, his thoughts on political economy receiving a stimulus from the agitation caused by Napoleon's decrees against British commerce, he issued a pamphlet, entitled "Inquiry into the Extent and Stability of National Resources." This publication had success sufficient to inspire him for a time with the idea of coming to London to increase his literary connections. Reverting to this idea, he continued at Kilmany, with a growing reputation for various attainments, as well as for extraordinary energy, accompanied with some eccentricity, of character and manner. In 1809 he made his first speech in the General Assembly of the Church of Scotland, in a speech of many of his oratorical triumphs in after life. In the same year he became a contributor to the 'Edinburgh Encyclopaedia,' under the editorship of Dr. Brewster, now Sir David; and it was partly to his studies while preparing an article on "Christianity" for that work, and partly to the solemnizing
effects of a severe illness which, during the winter of 1825-6 brought him to the very brink of the grave, that at first seemed as if it must be his last. Then, for the first time, as he thought, he saw Christianity in its true light; and then for the first time also he saw the duties of the clerical office, as he thought, sufficiently deepened. He immediately applied himself to the study of this, that whereas hitherto he had belonged to the 'Moderate' party in the Scotch Church then in the majority, he now ranked with the 'Evangelical' party, which formed but a minority. But the fruits of the change were more immediate in his literary and oratorical than in his clerical duties. Not giving up his studies in natural science and in political economy, but carrying them on with the same zeal as before; contributing also to the 'Christian Instructor,' the 'Literary Review,' and other periodicals—it was not observed that in all that Mr. Chalmers did the influence of a deep sense of religion, and a conviction of the paramount claims of Christian faith on the thoughts of men, were discernible. Always eloquent in the pulpit, his eloquence now burst forth in strains of such passion and fervour as he had never been heard from him before; and from far and near people went to hear the wonderful minister of Kilmany. Bible and missionary societies, for which he had formerly cared but little, now occupied much of his attention; and, instead of giving up his parochial duties, he began to hold sermons from the pulpit, he began a regular organisation of his parish with a view to make himself familiar with the interests of every individual in it, and to provide for all its spiritual wants. But amidst all these new occupations, which he prosecuted with his constitutional enthusiasm, he married, in 1812, Miss Grace Pratt, the daughter of a retired captain in the army. In 1819 his article on 'Christianity' appeared in the 'Edinburgh Encyclopaedia,' and in the same year it was published, with additions, in a separate volume as a treatise on 'The Evidences of Christianity.' The following two years were spent in asiduous parochial work, in theological studies, and in the composition of occasional works on various topics, including one on the reconciliation of scripture and geology.

The name of Mr. Chalmers was pretty well known over the south of Scotland as that of a man of powerful mind and extraordinary eloquence when, in 1815, or in the thirty-sixth year of his age, he was called from his quiet country parish to assume the pastoral care of Tron parish in the city of Glasgow. He remained in Glasgow in all eight years. In 1816 the degree of D.D. was conferred on him by the University of Glasgow. From 1816 to 1819 he was minister of Tron parish. From 1819 to 1823 he was minister of the newly constituted parish of St. John's. These eight years were the period of his highest celebrity as a pulpit orator, his name and fame were all Glasgow rang with his name. One of the most enthusiastic descriptions in Mr. Lockhart's account of Scottish celebrities at that time, published under the title of 'Peter's Letters to his Kinsfolk,' is that given of Chalmers in his Glasgow pulpit. A picture so elaborate and glowing from such a pen of a man whose position was simply that of a Presbyterian clergyman of a Glasgow parish, proves that already he was no longer thought of only in that capacity, but as a man of truly great genius, not what it is, "as Jeffrey, in 1816, "but there is something altogether remarkable about that man. It reminds me more of what one reads of as the effect of the eloquence of Demosthenes than of anything I ever heard." The same impression was afterwards published by all Glasgow. All Scotland—on Haslitt, Canning, Wilberforce, Hall, and Foster. Part of the secret was that Chalmers was not one of those orators whose power vanishes in the moment of their actual utterance, but a man of massive, large, and substantial thought, whose every speech was the enunciation and illustration of some principle or generalisation, and whose language was full of extraordinary felicities, memorable turn of phrase, and gleams of poetic conception. Perhaps the first large manifestation of this was in his sermons on the topic of high intellectual attainments and general literary genius with the specific qualities of the orator, was conspicuously brought out, was on the occasion of the delivery, in 1816, of a series of lectures on Astronomy and Religion. The excitement caused by these 'Astronomical Discourses' was unprecedented; and their popularity, when published in the same year, rivaled that of the contemporary 'Waverley Novels.' But his regular pulpit sermons were no less extraordinary as displays of mental and oratorical energy. It was to this that they gave rise. London, and other places, his fame as an orator preceded him, and drew crowds to hear him. At Edinburgh his oratory was exhibited not only in the pulpit, but also in the debates of the General Assembly, in which he was induced to take part. He was a member of the assembly, and contributed to the debates of the reform parliament of Scotland. Here as a leader of the 'Evangelical' party, then gradually gaining influence and influence, he took a polemical part in some of the Scotch ecclesiastical questions of the time, and always with the effect of a man of the highest talents and of the most earnest and prayerlike"—which, in his own characteristic language, "rites home of its sweets, and by elevating a man above his fellows, places him in a region of desolation, where he stands a conspicuous mark for the shafts of malice, envy, and destruction; a popularity which, with its head among storms, and its feet on the treacherous quicksands, has nothing to look the agonies of its tottering existence but the hoarsannahs of a drizzling generation." Far more important in his own eyes than these pulpit services which brought him fame, were his sermons and his addresses, which exhibited the social efficacy of Christianity. It was Dr. Chalmers's fixed and lifelong belief that in religion alone was there a full remedy for the evils of society, and that all schemes of social amelioration would be useless until the Christian spirit had permeated the hearts of the people down into their habits and households. Subordinate to this belief was his attachment to the parochial system of social organisation—that system which divides a community into small manageable masses, marked out by local boundaries, and having a sufficient ecclesiastical and educational apparatus within itself. Disliking with his whole heart the English Poor-Law system, he was of opinion that, if the parochial system were properly worked, pauperism could be provided for without a poor law at all, by the judicious direction, under clerical and lay superintendence, of private benevolence. In order practically to illustrate these views, he undertook a vast experiment, first with Tron parish, and then with that of St. John's. The population of this latter parish (in which Edward Irving was for some time Dr. Chalmers's assistant) was upwards of 10,000, including perhaps the poorest part of the operative population in Glasgow; but such was his zeal, such his practical sagacity, and such his power of influencing persons to be his agents, that in a short time the parish was organised both for economical and educational purposes in a manner unknown before, schools being set up in every part of it, and the poorest lanes visited periodically each by its own special teacher. His views, his teachings, and all that he did, were, in his speculations in connection with it, were published by him (1819-1823) in a series of quarterly tracts, on the 'Christian and Civic Economy of Large Towns,' which, with two volumes of 'Sermons,' published respectively in 1820 and 1823, two articles on 'Panperitism' contributed to the 'Edinburgh Review' in 1817, and a sermon in the same year on the death of the Princess Charlotte, formed along with the 'Astronomical Discourses' already mentioned, his chief literary exertions during his residence in Glasgow.

In the midst of the bustle and fatigue of his life in Glasgow, increased ten-fold by the hospitality which his celebrity obliged him to exercise, Dr. Chalmers had never ceased to sigh for the academic quiet of a professor's chair in one of the universities, and to address himself year after year to the surprise of the public, he resigned his charge, and accepted the chair of Moral Philosophy then vacant in his native University of St. Andrews. The new post was one of much less emolument, and the writer of the life on which he had resigned, but even had his tastes not disposed him to accept it, had it paramounnt reasons in the state of his health, which was giving way under the wear and excitement of city-life. Forty-three years old when he accepted the chair, he continued his residence in the university for eight years. The winters of these five years were spent by him in the preparation and delivery of his class-lectures, and in the genial society of many of his old friends; but he carried with him a gentlemanly ease and affability, which he had matured in Glasgow, and the little Fife-shire town felt during these five years the vivifying influence of his spirit and enthusiasm. Occasionally he preached in
Andrews and in the neighborhood round; annually in May he visited Edinburgh to take part in the business of the General Assembly, where his eloquence as before was felt as a conquering force on the 'Evangelical' side in all the great controversies of the day. Non-Intervention in Church and State was the general feeling in Scotland and Ireland, and journeys as far as London, varied its summer. It was proposed at one time to elect him to the Moral Philosophy chair in the newly-established University of Edinburgh, but he was not occupied in defending his view of the proper relations between Church and State. Of this controversy Dr. Chalmers was, on one side, the chief champion; and for several years he was engaged in preparing, and occupying a leading part in the discussion of the questions in dispute in speeches both against the 'Moderate' party in the church itself, who had from the first opposed the Veto Act, and also against the civil courts and the government. More than once it seemed to them that the breach which had been made was in danger of being quiet to Scotland; but at last, these hopes being over, the struggle was ended at the meeting of the General Assembly in the 15th of May 1843, by the so-called 'Disruption'—i.e. by the voluntary secession of upwards of 400 clergymen, followed by a large portion of the people of Scotland from the Established Church, and the institution of a new ecclesiastical body called the 'Free Church.' At the head of this secession was Dr. Chalmers, who was nominated moderator of the first General Assembly of the new church.

The last four years of Dr. Chalmers's life were spent by him as Principal and Professor of Divinity in the New College founded by the adherents of the Free Church for the theological education of ministers. (The University of Edinburgh having been necessarily vacated by him on his secession from the establishment). During these years, too, he exerted himself prodigiously in arranging the organization of the new church, and in raising funds for its support; and probably at no period of his life was he more truly a centre of his intellect, his power of dealing with new social emergencies, and of leading men, more conspicuously shown. He had seen the foundations of the new church laid very carefully, and was preparing using in the work of completing its organization into the hands of his many able and younger colleagues, and to devote the rest of his days to his labours as a theological professor, to Christian and philosophical literature in connection more immediately with his the 'North British Review,' then started under his superintendence, and to a new experiment of Christian philanthropy which he had begun in one of the most wretched quarters of the town of Edinburgh, when death removed him. He had just returned from a tour of the present excellent health and spirits, to take part in the proceedings of the General Assembly of the Free Church, when on the morning of the 31st of May, 1847, he was found dead in his bed at his house at Morning-side, near Edinburgh. Of Chalmers's system of religious principles no one who had the advantage of his acquaintance, or who had been occupied in any way, knew the works of Dr. Chalmers have been put forth in twenty-five volumes, and who has also written his life in four volumes, and edited much of his correspondence.

Dr. Chalmers was a man of powerful frame, not tall, but massively built; his head was very large. It was remarkable in a man so celebrated over Britain or as an orator, that he always spoke not only in a broad Scottish, but also in a broad provincial Scottish accent, mispronouncing almost every word. Perhaps it is because his Scotch accent, his accent, and sociable manners, with a great fund of anecdote and broad humour. His works, notwithstanding the force of his intellect that they show (and his speculations in social and political economy, in particular), are valued by many of the best thinkers of the day who have no sympathy with his theological or ecclesiastical opinions), but faintly convey an idea of what the man was while he lived, and of what he still is in the memory and imagination of the Scottish people. He is variously characterized by having a 1-celled ovary, ascending ovules, dotted leaves, and the embryo fused into a solid mass. They are usually small bushes with very few leaves, the flowers have a close resemblance to heaths. All their parts are abased in glandular oily cavities. They are mostly regarded as belonging to Myrtaceae, and there is no doubt of their affinity to that order. Their peculiar aspect, abortive stamens, simple ovary, and pappose calyx sufficiently distinguish

R. B

CHA CHA
them. They have the fragrance of *Myrtacea*. Fifteen genera and fifty species are included in this order, all natives of *Myrtacea*. Their position, according to Lindley, is between *Asteracea* and *Combretacea*, near to *Myrtacea*. (Lindley, *Familles Köslers.*

**CHANCEY, COURT OF.** There are now three Vice-Chancellors (6 Vict. c. 5; 15 Vict. c. 4), before whom and the Master of the Rolls sit in this Court are originally held at Westminster, and for the distribution of the business is made the same, according to the statute. 15 & 16 Vict. c. 83, which consists of two Lords Justices; who may either themselves, or conjointly with the Lord Chancellor, exercise all the appellate jurisdiction of the Court, and so the Chancellor, and himself sitting or with a Master, in such cases as the Lord Chancellor is in the whole delay which has always been the standing reproach of this Court was thought to have, have been abandoned, their functions being now performed by the Master of the Rolls and the Vice-Chancellors, assisted by their chief clerks, in their own chambers (15 & 16 Vict. c. 80). The procedure of this Court generally and its jurisdiction in many respects have been subjected to great changes of late years, as to which see EQUITY, BANKRUPTCY, Trusts, CHARTERS, LONATUR, Just-Stock Company, all in S.

**CHADINDEE,** Chaotic Plants, a family invented by Boré, for the purpose of placing a number of the lower forms of plants or organic beings of uncertain character, which cannot be assigned to any of the several well-defined groups of *Cryptogamia*. To this family were assigned forms of *Dictamene*, *Dorideae*, *Nostoc*, and others.

**CHAR.** or **CHARIT,** one of the British species of the genus *Salmn*, of the Salmon tribe (*Salmo salarum*).

**CHAOS.** (Greek.)

**CHARITIES.** [Uszn., S. 2, Trusts, S. 2.] By the Charitable Trusts Act 1833, a body of commissioners has been created for England and Wales, with power to inquire into all charities, their nature, objects, and administrations, and the condition of the property belonging to them, to require the production of accounts and documents from the Trustees of charities, and to cause inspectors to visit and report on their management. No proceeding with reference to any charity can be taken but on the application of the Attorney-General, or of any person interested, for the purpose of removal of the Trust or the sale of its property, which is called 'The Charity Commissioners for England and Wales.' The Attorney-General alone may proceed by ex officio information. The board may direct in what court proceedings for the administration of any charity are to be taken; but where the income is not over 30l., the County Court of the district, or the Court of Bankruptcy of the district in which the charity is situated has jurisdiction. In other cases the Court of Chancery must be resorted to. If the charity be one granted by the Crown, or the Ireland, to the Universities, or the City of London. A report of the proceedings of the Board must be annually laid before Parliament.

**CHASÉ, DAVID HENRY, BARON.** The military defeat of the Spanish in the Peninsular War, and the loss of the Spanish fleet in the battle of Trafalgar, caused a great change in the military system of Spain, and the appointment of Mr. Chasé, as a member of the Spanish government, to visit the north, was the result of the action of the English government, which was then in the hands of the Pitt administration. Mr. Chasé was sent to the north, to report on the state of the army of the north, and on the state of the country. He was at first a member for the north, but after a careful education for that calling, he entered the army as an independent member, in 1785. After various adventures, he appears to have visited Paris shortly before the Revolution, and to have witnessed the capture of the

**BATTLE at 1780.** His eccentric disposition took him to America in 1791, to look for the North-West Passage. He spent several months in the States, with an interview at Washington, visited the falls of Niagara, and roamed through those forests and wild scenes of primitive life which he has described so vividly in 'Rény' and 'Aita.'

On his return home he joined the army of Condé for a short time in 1792, and the next year he began a life of great adventure, which brought him through the Peninsular War, the war of the Revolution, and the war of the Empire, to the march of Napoleon. The best account of his life, which he has left, is in Chateaubriand's 'Memoirs,' almost incredible. Nevertheless he continued in England nearly eight years, maintaining himself by translating for Lord Byron, and became, in 1797, he published in London his 'Essay on Revolutions,' a work full of scepticism: but the death of his mother in 1798 gave a new turn to his thoughts, and restored his faith. In the spring of 1800 he went to Paris, and his old friend, M. Fontanes, whose influence was already strong, had been appointed one of the editors of the 'Mercure,' in the columns of which 'Aita' appeared for the first time. This romance was followed by the 'Genie du Christianisme' in 1802, which made a deep impression on the public mind. The First Consul was so pleased with this work that he took the author into favour, and strove to bend him to his service by two successive employments. Unfortunately the executors of the late Duke of Buckingham, however, refused the proposal, and the First Consul found it impossible to obtain the release of Chateaubriand with too just an excuse, and he resigned his appointment the same day. Fontanes, Madame Bacciochi, and even Josephine herself, could scarcely prevent the consequences of this rash act from falling on Chateaubriand.

In the following articles the number of atoms of each element in a compound body is added. In order to ascertain the relative weight of any element in a compound, the number of atoms of each must be multiplied by its equivalent weight and then the quantity of each element in a given weight of a compound may be ascertained. Most of the references refer to other names, given in the present article; where they refer to previous articles in the Penny Cyclopaedia, P. C. is added.

Absinthium, is an active or bitter principle found in Absinthium Artemisia. It belongs to the class of non-oxidised vegetable secretions. It is neutral in its relations to acids and forms a semicrystalline mass which is insoluble in alcohol. It is intensely bitter to the taste. The same principle is also present in the other species of Artemisia, which have to a certain extent the bitter taste of A. Abnichtium.

Acronytite, C6H7N, is one of the compounds obtained from methyl. It is procured by distilling the double sulphate of potash and methyl with cold water, and then adding potassium carbonate, to the filtrate, until a precipitate of potassium. It is a colourless volatile liquid, has a slightly allacaceous odor, and is somewhat stupefying in its effects. It is very combustible, and when heated with potash it yields ammonia and the salt of potash. Its elements may also be found in the form of a cyanide of methyl C6H5 + CN, and this compound is usually placed by chemists in the series of methyl compounds. (Chemistry, P. C., S. I.)

Acetic, C2H4O. The first effect of the oxidation of ether or alcohol is to produce a compound radical which is acetic. It is however unknown in a separate form, but is easily obtained in the form of a hydrated protodite which is called Aldehyde, C2H4O + H 2O (Chemistry, P. C., S. 1.) or in the form of the hydrated peroxide which is acetic acid C2H4O2 + H 2O. [Acetic Acid, P. C.]

Hydrobromate of Acetylene. May be regarded as the base of other compounds than those of aldehyde and acetic acid; thus oleifant gas or ethylene, C2H4, may be expressed as C2H4 + H 2O, or a hydrobromate of acetylene. (Chemistry, P. C.)

Oxocarbonyl of Acetylene. When ether and dry chlorine are acted on by the sun's rays several compounds are formed, and amongst others this substance. Its composition is C2H4O + O + CI. It has in fact the same composition as acetic acid, but in two equivalents of the oxygen of that compound are supplemented by two of chlorine.

Perchloride of Acetylene, C2H4Cl. This compound is also formed by the action of chlorine on ether, and has the same composition as acetic acid, the whole of the oxygen being substituted by chlorine.

Acids, Organic. The acids met with amongst organised bodies differ in their elementary constitution from the inorganic acids, but are generally formed on the same plan. They are mostly composed of the three elements, Carbon, Oxygen, and Hydrogen, and the theory, in which Nitrogen is not unfrequently added. The proportions in which these elements unite render the atomic numbers of the organic acids much higher than those of the inorganic acids, in which the difference is diminished and in the case of Sulphuric Acid and Nitric Acid, unite in but one single proportion with several proportions of oxygen. The organic acids are easily decomposed by heat, whilst the inorganic acids resist this agency much more. The acetic and citric acids are easily decomposed by heat, but sulphuric and nitric acids resist its action.

There are two theories of the nature of organic acids, by which they are made to harmonise with the constitution of inorganic acids. In the first place, like sulphuric and nitric acids, they are regarded as oxygen acids. In this case, a compound radical is assumed which combines with the oxygen, and forms the acid which, to constitute the ordinary liquid acid, must unite with water. Thus, to take sulphuric acid. One part of sulphur combines with three of oxygen to form the dry acid, which must unite with water to form the liquid acid. Thus S O + H 2O represents the common hydrated sulphuric acid, or oil of vitriol. We may take acetic acid as an example of the organic acid. The compound radical which represents the sulphur of the sulphuric acid is acetyl (C + H 2O). This combines with three parts of oxygen and forms the dry acetic acid. But in order to have the liquid acid there must be an equivalent of water. The two may thus be compared:

<table>
<thead>
<tr>
<th>Salt</th>
<th>Acid</th>
</tr>
</thead>
<tbody>
<tr>
<td>S O + H 2O</td>
<td>Acetic acid (C2H4O2 + H 2O)</td>
</tr>
</tbody>
</table>

This analogy between the organic and inorganic acids may further be pursued through the whole series. There are, however, many cases in which this theory cannot be proved to be true, in which, in fact, the water cannot be withdrawn and replaced with the facility which the above theory requires.

This has led to a second theory, which is becoming more generally adopted at the present day. It applies equally,
however, to the ioagricic as to the organic acids. It is very obvious that this compound may be arranged as \( SO_3^- + H^+ \), and that such a change may be effected in the expression of any of the acids. In this view of the composition of the acids, the hydrogen, not the water, is the removable element; and it would appear from experimental researches that the water does not exist at all. This theory is more compatible with the real condition of the acids than the first. This constitution is as easily applied to the organic acids as the other. Thus, instead of the above formulary, we may write:

- Sulphuric acid, \( SO_3^- + H^+ \).
- Sulphate of soda, \( SO_3^- + Na^+ \).

The sodium is the place of the hydrogen.

In the constitution of the polybasic acids this theory is more strongly confirmed. Thus phosphoric acid was supposed to assume three forms, according as it united with one, two, or three atoms of water, and these were called mono-, di-, and terhydrated. But Professor Graham showed that it would be better to regard these acids as combined with one, two, and three atoms of hydrogen, and proved that the phosphoric acid in its three forms united with metals by taking the place of the hydrogen of the acid.

That the old formule for the organic acids may be easily reduced to the new is seen in the following examples:

**OLD.**
- Tartaric acid, \( C_4H_6O_6 \).
- Malic acid, \( C_4H_6O_7 \).
- Citric acid, \( C_6H_8O_7 \).
- Meconic acid, \( C_5H_6O_7 \).
- Saccharic acid, \( C_6H_12O_6 \).

**NEW.**
- Acirolein, \( C_4H_6O_7 \).
- Acrolein, \( C_4H_6O_7 \).
- Acrolein, \( C_4H_6O_7 \).
- Acrolein, \( C_4H_6O_7 \).
- Acrolein, \( C_4H_6O_7 \).

**In such acids there is always some hydrogen in the radical, of which it is a constituent, and some combined with the radical, which may be replaced by the metals. Amongst the organic acids, there are some facts which seem to show that this replaceable hydrogen exists. Thus, meconic acid, which is the most easily used, on heating with potassium hydroxide, forms three series of salts, in which one, two, or three equivalents of the hydrogen are replaced by the metal. But while the meconic acid, as well as the tribasic phosphoric acid, readily forms with citric of the silver, the salt of meconic acid may be replaced by silver; it cannot form, or form with difficulty, a similar salt with potash, with which it forms very easily salts with one and two equivalents of metal, and two or one equivalents of hydrogen.** (Gregory). This fact is difficult to be accounted for on the old theory, while it meets with an easy solution on the new. The oxide of silver easily parts with its oxygen, and there is no difficulty with it in substituting three atoms of silver for three atoms of hydrogen, but the potash does not unite with the silver so easily that the oxalate will not form the compound with three equivalents of potassium.

**Acrolein, \( C_4H_6O_7 \).** A substance obtained by Redten- bacher by the distillation of glycerine with phosphoric acid. The operation must be carried on in vessels charged with carbonic acid gas, as acrolein is so rapidly oxidized in atmospheric air, that it cannot be obtained where it is present. It is a very pungent and suffocating substance, attacking the eyes and nose of the operator if care is not taken. It is composed of carbon, hydrogen, and oxygen, and may be regarded as the hydrate of carbonic acid, and the caloric acid. This substance resembles acetylene, and represents in acrolein the position of acetylene in aldehyde. Thus, \( C_4H_6O_7 \) + \( H_2O \) is the atomic constitution of acrolein. But this substance behaves as the carboxylated acid, it is converted into acyllic acid, \( C_4H_6O_7 + H_2O \), a substance perfectly analogous to acetic acid. Acrolein is often formed as the result of the distillation of oils and fats. Thus, castor oil yields acrolein, and some other peculiar products on distillation. Glycerine may in fact be regarded as an hydrated oxide of acrolein with three additional equivalents of water, as follows:

- Glycerine, \( C_3H_5O_3 \).
- Hydrated oxide of acrolein, \( C_3H_5O_4 + 4H_2O \).

cost however has been very considerable on account of the price of the metals by which it is obtained. Sodium is preferred in preference to potassium, but the metal has first to be obtained by costly processes. These last have been greatly diminished, so that sodium has been recently sold for 10. a pound. This still renders the price of aluminium a barrier to the general use of that metal. Nevertheless it has been extensively used in Paris into spoons, tea-pots, coffee-pots, and other articles of use. In order to obtain aluminium, the chloride is introduced into iron tubes and heated with the sodium.

The chloride of aluminium, from which the metal is prepared, is not a natural compound, but has to be made from the earth aluminas. It is prepared by mixing this earth, freshly precipitated with some form of carbon or carbonaceous substance, as charcoal, sugar, tar, &c., and the whole is made into a paste with water. The paste is then exposed in a crucible, and placed in a tube and exposed to the action of dried chlorine gas, when the chloride of aluminium is sublimed and collected by condensation. It has a straw colour, is soluble in water and crystallizes in isomeric isomers according to temperature, and combines readily with water, from which it is not separated by any means.

Amphemane, another name for Amiline. [Aniline.] Amabile, C₈ H₈ N₄ is one of the bases obtained from oil of bitter almonds, is used in the decomposition of tar, (C₄ H₆ N₂), with which is isomer, by boiling the latter with potash. Amarine forms fine white needles; it is insoluble in water, but soluble in hot alcohol. It has the properties of a powerful oxidizer.

Nitro-indigo-acid, C₈ H₈ N₂ O₃, is one of the products found in the colouring matter of lichens.

Amasine, C₈ H₈ N, one of the numerous bodies formed by the decomposition of indigo.

Amine, a fat, analogous to olestearine, found in ambergris. When treated with nitric acid it yields acminyl acid.

Aniline, C₈ H₈ N. A compound radical, discovered by Frankland. It is procured by the action of zinc on isatin, a substance of the earth oxides, which in its natural state is found in Paris under the name of Barks. It is procured by the long continued action of weak nitric acid on that substance. It is also obtained in the preparation of Indigo. The substance is identified with aniline. The same distinguished chemist has added largely to our knowledge of this substance. He has shown that isatin, which is oxidised blue indigo when treated with potash, yields aniline, and that chlorosine and bromosatine when treated in the same way, yield products of the type of aniline, in which hydrogen is replaced by chlorine, bromine, or both. Aniline assumes a deep violet colour when heated with chlorine, and is used for the purpose of making indigo, and for its power of entering into combination with other substances. Hofmann has obtained it from other substances besides isatin. When anthranilic acid is treated with powdered glass, it is resolved into carbonic acid and aniline. Aniline is distinguished from nitro-indigo-acid by the fact that it is not soluble in alcohol or aqueous solutions when exposed to heat with the bases lime, or baryta. The first yields little, but the last compound is entirely resolved into aniline and carbonic acid. The following is a list of substances which are formed by the simple substitution of other elements for atoms of hydrogen in the aniline base.:

- Aniline: C₈ H₈ N
- Dichloraniline: C₈ H₈ Cl₂ N
- Trichloraniline: C₈ H₈ Cl₃ N
- Bromoaniline: C₈ H₈ Br N
- Dibromaniline: C₈ H₈ Br₂ N
- Tribromaniline: C₈ H₈ Br₃ N
- Chloromethylaniline: C₈ H₈ Cl N
- Nitroaniline: C₈ H₈ N₂ O₃
- Nitrodibromaniline: C₈ H₈ BrN₂ O₃

Chemically, these compounds are of the highest interest. In the case of aniline, bromoaniline, and chloroaniline, chlorine and bromine are substituted for hydrogen, and this was one of the first instances known of the substitution of other elements for hydrogen in a basic compound, although many instances have since occurred. It will also be seen from these compounds that aniline has a close resemblance to ammonia. In the fact, that just as ammonia forms the compounds carbadamide and oxamide, so aniline will yield under the same circumstances carbarnilide and oxamidine. It also forms acid anilines, as carbanilic acid, analogous to the discovery that just as cyanate of ammonia passes into azide, and the cyanate of methylamine into methyl-urea, so cyanate of
aniline passes spontaneously into anilino-resorcin. For a full account of the chemistry of this highly interesting compound, the reader should consult M. Berzinskis's papers Dr. A. Berzinskis (Chemistry—Benzole and Aniline Chemistry—Benzole and Aniline). Anilino-Acid, C₈H₇N₄O₂H₂O, a compound of aniline and cyanic acid. 

Anilino-Lycones, C₈H₇NO₄, a compound of aniline and mellolone, obtained by the heating of anil. Anilino-Acid, a substance obtained by acting on the oil by strong acids, or the chlorides of tin or antimony. It is analogous to benzene.

Antiseptic = Phenomenone = Corrosol of oxides of Methyle, C₆H₅NO. This is one of the many compounds of the oxide of methyle (C₆H₅O). It is obtained by heating anisic acid, which is itself obtained by oxidising the stearene of oil of anise with nitric acid. Antiseptic is the radical of anisic acid, which is thus composed, C₈H₇O₄.

Anisine, C₈H₇N₂O₂. An alkaloid found in a cinchona bark from Arica in Peru. It is similar in its properties to Cinnoline.

Anisine, C₈H₇NO₄, is a volatile principle, obtained from the Anisum Europaeum. It has a remarkable tendency to crystallise in beautifully definite forms. It however readily assumes an amorphous condition, from which it is again easily restored to its crystalline condition. The facility with which, under appropriate conditions, for the crystallisation in general, has been taken advantage of by Schmidt, who has published a paper on the microscopic appearances of this substance during its crystallising condition in the 'Annalen der Chemie und Pharmacie,' for February, 1845.

Anisine, C₈H₇O₄, is a fatty body, obtained from the root of Althamaam orientale. It contains valeric anhydride, united to a base called Oresoleum. Athamantine combines with hydrochloric acid, and the compound, when boiled, deposits crystals of combined water (C₈H₇O₄) a compound that is isomeric with benzoic acid.

Atomine, C₆H₇NO₄, is this substance is an alkaloid, and it is found in the Atropa Belladonna. It crystallises in white silky prisms, which are sparingly soluble in water and ether, but more so in alcohol. It is very bitter, acid, and poisonous, and, like the extract and juice of the plant, dilates the pupil of the eye when taken or applied to the eye externally. It is fusible and volatile, and forms salts with the acids, which are bitter and poisonous. This alkaloid, like many others, is much the most certain form in which the belladonna can be applied for medical uses.

Asmeline, an alkaloid found in the Melia Asmelinea. It forms a compound with sulphuric acid, and is said to be a powerful seirife. Azo-berenyle, C₆H₇N₂, a compound obtained by Laurent from the oil of bitter almonds. Its base is benzoyl combined with nitrogen. Azo-anime, one of the acids formed by the action of nitric acid on oleic acid.

Balsam Arom. C₆H₇O₂H₂O. A fatty acid melting at 164°. Basic Arom., C₆H₇O₂HO. This acid combines like the other fatty acids with oxides of glycercy, or lipoxy, and in this state is present in the butter of Basser Isafiel, one of the butter trees of Africa, and in the fat of Coctis Indicus. It is a crystalline fatty acid, melting at 150° Fahr. It forms soaps with the alkalies. With chlorine it forms chlorobasic acid.

Berezine, C₆H₇O₄, is an alkaloid, and the active principle of the bark of the Beezroot tree of Guiana. The bark of this tree has been found an excellent substitute for cinchona. The resin itself is employed as a substitute for quinine. Planta obtained it in the form of a slow-white, crystallisable powder. Its salts are not crystallisable, and they all act as seirife.

Benzamine, C₆H₇NO₄. This is a compound of benzoyl (Chemistry—Benzole and Aniline Chemistry—Benzole and Aniline) and amine. It is formed when dry ammonia acts on chloride of benzoyl, also when hippuric acid is boiled with peroxide of lead. It forms fine soft needles or powder, very fusible and volatile. It yields ammonia with nitrous acid, and the base, and a benzole is formed.

Benzene = Benzole = Benzol. [Chemistry—Benzole, S. 1.]

Benzamidine, C₆H₇NO₂. This is one of the numerous compounds described by Laurent as the result of the study of hydrocarbons of bitter almonds. It is found in the oil in a crude state. It is crystallisable, and is decomposed by acids into benzoic acid and ammonia.

Benzoin, a name synonymous with Toluol. [Toluol.]

Benzoylglucic Acid, C₆H₇O₂H₂O + HO. This acid is formed when benzoyl and alcohol are heated in the presence of Dr. A. Berzinskis. A compound of benzoyl and alcohol. It is crystal-like, soluble in alcohol and ether, less soluble in cold water. When heated with acids it is decomposed, yielding benzoic acid and glycolic acid.

Benzole, C₆H₇O₂, a product belonging to the benzoyl series. It is procured by acting on crude oil of bitter almonds containing hydrogenic acid with an alcohol solution of potash or sulphate, or cyanide of potassium. It occurs in the form of small crystals, insoluble in water, and soluble in alcohol. Benzole is a crystallisable substance, which is a benzole isomer. It occurs in the form of small white needle-shaped crystals. It dissolves in acids, and is precipitated by alkalies.

Benzoinamide = Hydrobenzoinamide, is formed by exposing a mixture of benzene and ammonia. It is white, tasteless powder, and volatilises without decomposition.

Benzoil, C₆H₇O₂. When Hydrobenzoin (C₆H₇NO) is heated with potash till it becomes blackish brown, this compound is formed. The mass when washed with water separates into two parts, of which the upper is a yellow oil, while the lower gives a bright red colour when acted on by sulphuric acid.

Bolorett, C₆H₇ + 3HO. The name of one of four resinous compounds found in the peat of Denmark on the remains of pine trees. It is a fusible compound, but not combustible.

Bromial, C₆Br₂O + HO. This compound is analogous to chloral (C₆H₇O + HO), and is formed by the action of bromine on alcohol. It is resolved into formic acid, and becomes a powerful poison by compound action of caustic alkalics.

Bromatine. [Aniline.]

Bronaphtic acid, C₆(H₇Br), is one of the numerous compounds obtained from naphthaline. It is formed by the direct action of bromine on naphthaline, care being taken not to add the bromine to the naphthaline, for which reason the compound is called Bronaphtic acid. Naphthaline is a colourless oil, decomposed by chlorine and bromine.

Bronaphtic acid, C₆(H₇Br), is formed by the action of bromine on naphthaline, or on bromosine. It is a crystallisable solid, and forms several compounds with bromine.

Bronaphtic acid, C₆(H₇Br), is obtained by heating the bromide of bronaphtic acid.

Bronaphtic acid, C₆(H₇Br), a compound with the above formula, is obtained in two forms, which are said to be different.

Bottle = Falise, C₆H₇. This compound was discovered by Kolbe, as the result of the decomposition of valerianic or valeric acid (C₆H₇O₂) by the action of the galvanic current. It is a transparent, colourless liquid, insoluble in water, and soluble in alcohol and ether. It has an abnormally small, and a slightly acid, bitter taste. It is combustible, and burns with a bright but smoky flame. By the action of oxygen it is converted into butyric and nitropropprylic acid. Kolbe has obtained a substance, which he calls butyrene, and which is homologous with oleine and with propylene. It has the formula C₆H₇. It is found in oil gas.

Butylamine, C₆H₇N, has been discovered by Anderson in Dips's oil in company with ethylamine, methylamine, propylamine, and other bases. It is a volatile, oily, and powerfully basic substance.

Butyric, C₆H₇O₂H₂O + HO, was originally obtained by Guckelberger, amongst the products of the oxidation of fibre, &c., by sulphuric acid and peroxide of hydrogen. It is highly active in producing butyric acid.

Hydrated Oxide of Butyric, C₆H₇O₂H₂O + HO, was originally obtained by Guckelberger, amongst the products of the oxidation of fibre, &c., by sulphuric acid and peroxide of hydrogen. It is highly active in producing butyric acid.

Butyric acid, C₆H₇O₂H₂O + HO, is the hydrate of butyric acid, and perfectly homologous with other acids with a compound radical, as acetic acid. It exists in butter in small quantities, and is combined in them with acids. It is to this acid that the flavour of butter is mainly due. It can be obtained by fermentation from sugar or starch. The acid may be obtained from butyrate of lime by the action of sulphuric acid. It is one of the liquid substances, having a rancid smell. The rancidity of butter is due to this acid escaping, from its combination with the oxide of glycercyle. The butyrate of lime can be
obtained in any quantity by fermenting sugar with cheese and adding chalk. Carbo nic acid and hydrogen gases are set free.

Acetic-nitride = Cyanide of Propylene, C6 H5 N. It is a question whether this compound is a true cyanide, or a nitrile. It is formed among the products of the oxidation of aliphatic compounds.

Butyramidide, C4 H7 O N H2. This substance is produced by the action on the butyrate of the oxide of ethylene with ammonia in closed tubes.

Butyrene, C4 H7 O. This substance is homologous with acetone and propylene. It is less volatile than propione. It is prepared by heating the butyrate of baryta.

ded by the acid is formed from the cyanide of amyl- or camphorlyle by boiling it with a muriatic solution of potash. The filtrate of potash is obtained, which, on being distilled with sulphuric acid, yields capric acid, which is an oily liquid with a strong smell of perspiration. When united with the oxides of petroleum and petrol, it produces fragrant ethers, having the smell of melons, pine-apples, and other delicious fruits.

Caprons, C10 H20 O. From camphor, by heating the caprate of baryta. It is accompanied by caprylalde and caproal, C10 H22 O.

tes this substance obtained when unaethylic acid is decomposed by galvanism. It is a base similar to ethyle, and probably capable of similar combinations.

t of one of the compounds which gives flavour to this substance. It is an oily acid liquid smelling rancid, and having an odour of sweat. It boils at a high temperature.

Carbamic anhydride, C2 H4 O H O. This is a name given to cane-sugar when it has been exposed to a temperature of 450°. The sugar loses three equivalents of water, and becomes converted into a brown tasteless mass.

Carapine, an alkaloid found in the Carapa guianensis. It forms crystallizable salts with hydrochloric and acetic acids.

Cardamom, C ON H. This substance is produced by the action of chloro-carbo nic acid gas on ammoni. Sal ammoni ac is also formed at the same time. Under the influence of the minerals carbonates ammonium yields ammonia and carbonic acid.

Carbanalide, C6 O H N. This substance is used for the preparation of other species of Capsicum which are used in the manufacture of cayenne pepper. It has a pungent taste, and may be crystallised. It is insoluble in water and ether, soluble in alcohol. It forms crystallizable salts with sulphuric, nitric, and acetic acids.

Carmacine is a name given to succirubric acid.

Camphorine, C10 H16 O. When it is exposed to the action of heat, it first melts and then distills, and yields several oils which, like camphorine itself, are compounds of carbon and hydrogen. One of these is cuminole, which combines with chlorine, forming an oil very similar to camphor. This substance is formed when camphor is passed over red-hot lime.

Catechu, C10 O H N. This substance is used for the preparation of other species of Capsicum which are used in the manufacture of cayenne pepper. It has a pungent taste, and may be crystallised. It is insoluble in water and ether, soluble in alcohol. It forms crystallizable salts with sulphuric, nitric, and acetic acids.

Catechol = Tannin monochloride, C6 O H. It is that portion of catechu which is insoluble in cold water. It is soluble in hot water, and crystallises in the form of a white silky powder. When heated with caustic potash it yields a black acid called saponic acid. Carbonate of potash produces with it rubic acid (C6 H10 O3), which has a red colour.

Cassia, the native name of the various species of Cassia, which are used under the name of Cinnamon.

Ceyrek, one of the products of the distillation of coal tar discovered by Reichenbach. It is a volatile solid, and is obtained from the reaction of potash and acetic acid. It crystallises in a solution of a mixture of iron, forming orange red crystals, which dissolve with a blue colour in sulphuric acid. The colour of oil of tar seems to be owing to this substance.
CHED is that part of the gum of the cherry-tree which is insoluble in cold water. It is probably some transitional form between starch and gum.

Cheredd Acim is a substance said to exist in the fatty matter of the brain. It is accompanied by another acid, the olo-phosphoric acid, which is supposed to be united to a compound radical cerebrolene, in the manner of the fatty acids. These substances are of a very denatured nature, and the chemistry of the nervous system is at present in a very imperfect state.

Cherebnot. [Cherebon Acim.]

Chesan, C^6 H^4 O, is a solid wax-like body. It has been obtained as a compound of sulphuric acid with cetone, C^6 H^4 O + H O + 8 O.

Cheswee, C^6 H^4 O, is a waxy substance found on the surface of saols. It is not saponifiable.

Chesnorie, Acim, C^6 H^4 O + H O. This compound was discovered by Brodie as an ingredient of bee’s wax in a free state. It may be procured by dissolving wax in hot alcohol, and dissolving the residue deposited on cooling till its melting point rises to 162°. It is then purified by ether till its melting point is 171°, which is that of the acid. This substance was formerly called cereine. It has, however, acid properties, and combines readily with bases. It combines with alkalis, forming the compound of that substance, C^6 H^4 O + C^6 H^5 O, which is called cereitone. When heated with potash, it produces carbonate of potash and the hydrated oxide of cetye, or cetye alcohol.

Chlor, C^6 H^4 O, the base of cetye acid. [Chloro Acim.]

Cetale, C^6 H^4, a compound radical of the series C^6. It forms the following compounds:

Cetyl Alcohol = Ethyl, C^6 H^4 O H O. When spermaceti or whale oil is boiled with an alkali, a cetylate of the alkali is formed, and the hydrated oxide of cetye is left. Although a true alcohol, it is not liquid, but a fat, melting at a temperature of 115°. The crystalline part of spermaceti is called cetyl, and is a cetylate of the oxide of cetye.

Oxalic acid, COO H O, is produced by the action of sodium on cetye alcohol, when hydrogen escapes, and the remains being heated with iodide of cetye, yields iodide of sodium and oxide of cetye.

Some are in use, in which, C^6 H^4 O, is perfectly homologous with anphosphic acid: chloride, bromide, and iodide of cetye are also known.

Cetyl Acid = Ethanoic Acid, C^6 H^4 O + H O, is obtained from spermaceti by saponification, and adding some stronger acid to the compound. Its salts with the alkalies form soaps. It melts at a temperature of 131°.

Tertiaryamine, C^6 H^9 N, is formed when dry ammonia acts on iodide of cetye.

Cynanoic Acid is isomer with cetye acid, but melts at a temperature of 140°. It is the chief solid acid of palm oil.

Chelerythrine, an alkaloid found in company with Chelidonine in the celandine (Chelidonium majus). It forms a green, volatile, and violent ether. We form three salts with the acids, which are narcotic and poisonous. Chelidonine is a bitter substance, insoluble in water, and forming crystallizable salts.

Cinchonene, an alkaloid very similar to Vinic. The first is found in the snowberry (Chimona racemosa), and the second in the violet (Viola odorata). Their action on the human system is precisely similar to that of Emetine obtained from ipecacuanha. On this account it has been assumed that they are emetine disguised with foreign matters.

Chelaphosphate, C^6 H^6 Cl. This is the first of a series of compounds formed from Naphtaline, and described by Laurent. Naphthaline is composed of C^6 H^5. Laurent has shown that various elements will amputate the hydrogen, and that not only in one, but in several proportions. He has therefore proposed to give names to these compounds, according to the quantity of the element supplanted (the hydrogen). Then that in Chelaphosphate one atom of chlorine supplante one atom of hydrogen. According to the number of atoms supplanted, Laurent employs the vowels a, e, o, n, in the last syllable of the name. Thus, Chelaphosphate has one atom of chlorine, but Chelaphosphatone (C^6 H^6 O + 4 C^1) has three atoms, and Chelaphosphinate (C^6 H^6 Cl + H) has five atoms. When the vowels are exhausted, Laurent adds a syllable, so the compound C^6 H^6 Cl is

Chelaphosphate, the compound C^6 H^6 Cl, is Chelaphatisine. The same plan is pursued with bromine. But in all these cases the hydrogen may be replaced by atoms of both chloro and bromine. In the same way the vowels are made to do duty for these compounds, as follows: chelaphosphate, C^6 H^6 Cl; chelaphosphatone (C^6 H^6 O + 4 C^1) Br; chelaphorphosphate, C^6 H^6 Cl + 4 C^1 Br; chelaphorphatone (C^6 H^6 O + 4 C^1) Br; chelaphorphosphate, C^6 H^6 Cl + 4 C^1 Br. All these compounds are capable of acting as bases and combining with elements. Thus we have chelafide of charcoal, chelaphosphate of chelaphatisine, etc., bromide of chelaphorphosphate, etc.
COMPOUND Radical, a term applied to those combinations of the elements which act towards oxygen, hydrogen, and acids, as simple elements. Examples of such compound bodies will be found under the heads, amyle, butyl, cetyle, &c.

COLLOID. [Gen. Cottton.]

Creatine, C₆H₁₂NO₃. This body, originally discovered by Chevreul, occurs in transparent very brilliant crystals. It forms a crystallizing base, melting at 305°; and like that of pharynx. It dissolves in 7 parts of cold water, and in boiling water in such quantity that on cooling the solution becomes consolidated into a mass of glistening needles. It dissolves without change in all the alkalis in aqueous solution. It forms no definite salts with acids. According to Liebig it is best obtained from finely chopped flesh that has been well kneaded with water, and the fluid removed by pressure. The coagulable matters are then removed by boiling, and the phosphates by dilute baryta. The fluid left is then evaporated till the creatine is deposited in the form of needles. Creatine can also be obtained from the urine. It appears to be produced in the flesh of animals as the result of a process of retrogressive change in the elements of the tissues in which it is found. It is in fact a product of excretion.

Creatinine, C₆H₁₄N₂O₇, was discovered by Liebig. It is obtained from creatine by the action of hydrochloric acid. It is found also in the muscled and the urine, with creatine, whilst these bodies are in their normal condition. But in putrefaction either creatine is formed. Hence creatinisation may be regarded as the result of the decomposition of creatine.

Cumidine, C₆H₁₂N₂, is obtained from the oil of cinin. It is a crystallizing basic aniline, and like that base it combines with chlorine, bromine, &c. Cumole, C₆H₁₃, is found in the oil of cumin and in the oil of coal-tar. Cyanidine, C₆H₁₂N₂, and cyanole, C₆H₁₃, are found in commerce with the above compounds in the same oil. One of the curious properties of this substance is formed by the decomposition of cyanic acid when left to itself. It is an opaque white solid body, which has no acid properties. It dissolves in liquid potass with disengagement of ammonia, and the solution yields cyanate of potash.

Diosmine, C₇H₁₀O₂, is obtained by heating oil of turpentine with lime. It is a pure oil.

Diamylamine. [Amlte.]

Dihydroamineline. [Amlte.]

Dihydroaminoline. [Amlte.]

Diole. [Amlte.]

Dithylene. [Cyclamidic Acid.]

Elastic Acid, a fatty acid, obtained by the action of nitric acid on oleic acid.

Ethylen. When aldehyde is kept for some time in sealed tubes, it is converted into two polymeric bodies, methylethyle, a hard crystalline inodorous solid, and ethylene, which is a liquid.

Ethylic Acid = Oricinalonecarid acid, C₃H₆O₃. One of the acids composing the lichen, Roccella tinctoria, lichens which yield the commercial substance arbutin. This acid is the most important of all the principles found in lichens. It yields ether when boiled with alcohol. Besides ethylic acid, lecanoric, alpha orotic, beta orotic, and reccoric acids have been found in lichens. They yield red dyes with ammonia, and are employed extensively in the dyeing of cotton and woollen cloth. These acids have been investigated by Scharnck and Stenhouse, and the latter recommends the use of these lichens, in order to obtain ethylic acid, which and which are not possessed by lichens in larger quantities than 2 to 12 per cent, should be separated on the spot where they grow, and thus spare the expense of the carriage of the useless parts. These acids are extracted by the following process:—The lichens cut in small pieces are moistened with water, and after standing half an hour slaked lime is added, and the mixture allowed to stand for a time. It is then placed in a vessel with a double bottom, the upper being perforated and the liquid displaced by caustic alkali, and left as long as necessary, when a deep purple red colour with bleaching liquor, a character belonging to all the acids which yield arbutin. The solution is then saturated with hydrochloric acid, and a gelatious precipitate falls, which is collected, and dehydrated, and is found to be the double salt from it by weak alcohol without boiling, which would form ether compounds." (Gregory.) Besides the acids there are three other compounds found in the lichens used for dyeing.—Orice, Piercrysthine, and Bryogromannite.

Oricine, C₅H₈N₂O₆, occurs in the form of large transparent crystals. It has a sweetish taste, and is very soluble in water. When mixed with ammonia and exposed to the air, it assumes a deep red colour; and when mixed with the fixed alkalies it has a rich violet colour.

Piercrysthine = Erythrin—bitter = Amaryrine, C₄₈H₆O₃, is formed when erythric acid, or the lichens containing it, are boiled in water.

Erythrone, C₂₄H₃₄O₁₈, is formed when piercrysthine is boiled with baryta. It is dissolved by water and alcohol. It forms large colourless crystals, which have a sweet taste.

Ethyl. [Cettle.]

Ether, Betic, [Cettle.]

Ether, Camphor. [Cammphoric Acid.]

Ether, Amylic. [Amlte.]

Ethylandimonine. [Ethylic.]

Ethyle, C₆H₁₂. One of the earliest known of the compound radicals, and the base of the well-known substances ether and alcohol. It was for a long time unknown except in combination. Frankland, however, at last succeeded in separating it by the action of zinc in closed tubes upon the iodide of ethyl. The following equation expresses this result:—C₆H₁₂ + Zn = Zn + C₆H₁₂. Part of the ethyle, however, is converted into zinccethyle, C₆H₁₂ + Zn, and another part into methyle and eloye. In the latter case the ethyle becomes C₆H₁₂ + C₆H₁₂. Ethyle is a colourless gas, having a faint, sweet, aromatic odour, with a bright flame. It has a specific gravity of 2.00394, and is condensed into a liquid with 2.1 atmospheres. It is perfectly analogous to methyl (C₆H₅), and according to the law which regulates the density of these compounds, its density is higher whilst its volatility is less.

Oxide of Ethyl = Ether = Sulphuric Ether, C₆H₁₈. This ether is occasionally found in nature combined with acetic, butyric, and other ethers, which are found giving results to such fruits as melons, and the burning of the grain. This compound is obtained from alcohol by acting on it with sulphuric acid. [Ether.] Ether is now known to be perfectly analogous to the metallic oxides, its compound base ethyle taking the part of the metal. Thus, as K O + A represents acetate of potash, and K O Br represents benzate of potash, so C₆H₁₂ + O = C₆H₁₂ O₂. This substance is formed when ether and water meet in their nascent state, as when some of the acid salts of ethyle are decomposed by heat. It is however produced during the fermentation of glucose, a longer, which is composed of C₆H₁₂ O₂. During fermentation this compound loses 4 atoms of carbonic acid and leaves behind 2 atoms of the hydrated oxide of carbonic acid. Thus,

| [Alcohol, P. C.]

 Chloride of Ethyle, C₆H₁₂Cl, is formed by saturating alcohol with hydrochloric acid, and distilling the mixture in a vapid-bath, when the chloride of ethyle passes over.

 Bromide, Iodide, and Sulphide of Ethyle, are analogous compounds, consisting of one atom of ethyle and one of the other elements.

Hydrosulphuret of Sulphuret of Ethyle = Merscaptan, C₆H₁₂S₂, or C₆H₁₂S + H₂S, is formed when the double sulphate of lime and oxide of ethyle is distilled with its own bulk of a solution of potash saturated with sulphureted hydrogen, and converted into K₂S + H₂S. It has a pungent and penetrating odour, smelling like the essence of onions concentrated. It adheres to the hands and clothes most pertinaciously, and is a most offensive subject to operate upon. Zete has a greyish-brown fluid of ethyle, C₆H₁₂ + Sr. Selenturet of Ethyle is formed when sulphuret of ethyle and potash is distilled with sodium in potassium. It is a volatile liquid, having an offensive alliaceous odour.

 Cyanide of Ethyle, C₆H₁₂ + C₂O = C₆H₁₂ N, is procured by heating cyanide or ferrocyanide of potassium with the double sulphate of potash and ethyle. It is a very offensive compound, smelling like putrid fish. It produces stupefaction when inhaled.

Oxide of Ethyle unites with sulphuric and phosphoric acid.
acids, forming sulphates and phosphates. *Nitrate of the oxide of Ethyle, C₂H₄O + N O₃*, is the Nitric Ether of carbo-nitrous acid, and the *Sodium Nitrite* of Nitric Oxide is a compound of Nitric Oxide and Sodium, and *Nitrous acid* is the gas produced by the decomposition of Nitric Oxide by heat.

**Carbonate of Oxide of Ethyle** = *Carbonic Ether, C₂H₄O + CO₂*, is an aromatic liquid, boiling at a temperature of 260°. It unites with carbonic acid of potash, forming a double carbonate of ethyle and potash, C₂H₄O + O₂K + CO₂.

**Carbonate of Oxide of Ethyle** = *Carbonic Ether = Oxidum of Ethyle, C₂H₄O₂N O₃*, is formed by the action of ammonia or Chlorocarbonate of Ethyl, C₂H₄ClO₂, with sal-ammoniac. It is distilled over, and crystallises on cooling. *Lactamide, Sarcoine*, and *Alanine*, are substances having the same composition, but assuming very different forms. The following is a list of some of the bodies formed from ethyle, or having this substance as their base. This list not only indicates the relations of ethyle, but of several other compound radicals which may be substituted for it.

**Oxalate of Ethyle** = *Oxalic Ether, C₂H₄O + O₂N O₂*.

**Acid Oxalate of Ethyle** = *Oxalonic Acid, C₂H₄O + O₂N O₂*.

**Oxamate of Oxide of Ethyle** = *Ethylamine, C₂H₄O + O₂N O₂*.

**Carbonate of Oxide of Ethyle** = *Benzoe Ether, C₂H₄O + CO₂*.

**Hippurate of Oxide of Ethyle** = *Hippuric Ether, C₂H₄O + N O₂*.

**Salicylate of Oxide of Ethyle** = *Salicylic Ether, C₂H₄O + O₂N O₂*.

**Cyante of Oxide of Ethyle** = *Cyanic Ether, C₂H₄O + N O₂*.

**Ethyle-urna, C₂H₄N O₂*.

**Ethylamine, C₂H₄N*.

**Diethyamine, C₂H₅N O₂*.

**Triethyamine, C₆H₁₃N O₂*.

**Tetrothylamine, C₆H₁₃N*.

**Methylisothylamine, C₆H₁₃N O₂*.

**Salicylic ether** is an acid, C₂H₄O + O₂N O₂, which occurs in the radicyle, C₂H₄O₂N, and formyle, C₂H₄O, are produced. (Acetic; formyl.)

**Excretin** is a substance discovered by Dr. Marce in the excretions from the human bowels.

**Peculiar** is a soluble volatile crystalline substance, found in the spoile of the Filtrum-gebhe, which is probably derived from the essence of turpentine, and has a composition C₂H₄O₂N.

**Formic Acid**. (Formyl.)

**Formyl.** C₂H₄ is a compound radical unknown in its separate condition. When hydrated oxide of methyl is distilled with sulphuric acid, water, and peroxide of manganese, a liquid is produced which contains a formate of the oxide of methyl, and a liquid called methylal, C₂H₄O₂.

The latter is regarded as a hydrated oxide of formyl, and it is found that this hypothetical base is capable of entering into combinations in the same way as ethyle, acetyle or methyl.

*Acrolein, C₂H₄O₂*, is a tercxfylle of formyl. It originally obtained its name from having been found present in the redant, (Formical ruga). Hence also the name of the base formyle.

This acid may be procured from pyrolytic spirit, C₂H₄O₂ + H₂O, by the loss of two equivalents of hydrogen, and the addition of two equivalents of water to C₂H₄O₂. It may also be procured by mixing starch or sugar with peroxide of manganese, water, and sulphuric acid, and distilling. It is found also under a very great variety of circumstances. It unites with lead by forming a formate of lead, and from this formiate of soda may be procured by the addition of carbonate of soda. It unites freely with most of the metals, and the salts when heated in closed vessels give off carbonic acid and carbonic oxide, leaving the pure metal. It unites also with ammonia, the base being formed of hydroxyl, carbonic acid, and water. *Chloroform = Tetrachlore of Formyle, C₂H₄Cl₂O₂*, combines with formyle and forms a very interesting series of compounds.
are nitric acid, water has disappeared, and the rest is cellulose. According to Porrett and Foscheiner, gun-cotton contains 88% NH₃. The cotton was immersed in water and then rinsed in the use of gunpowder, as in fire-arms its explosive force is found inferior, but in the blasting of rocks it possesses some advantages over gunpowder. Gun-cotton is soluble in other, and a compound is formed, to which the name nitrocellulose acid and nitrate is given. It is the greatest use in many of the arts, especially photography. On being exposed to the air the ether evaporates, leaving a thin transparent film behind. This is applied to wounded surfaces instead of gunpowder, and after the ether has been driven off, the cellulose acid may be introduced for balloons. In photography the collodion is mixed with the iodides to be acted on by light, and, being spread on glass, pictures from which any number of impressions may be taken, are produced.

HARMALINE, C₄H₆N₂O₁₃, is a resaloid occurring in the seeds of Peganum Pernum. They are united with phosphoric acid. Harmaline forms yellow salts with the acids, and is transformed into a red salt by oxidising agents. The harmalin red of commerce is the powder of the seeds. It is used in dyeing red, rose-colour, and pink. It is used in large quantities in Russia. Harmaline yields a number of substitution products, such as a-Karkandine, cyanoharmaline, &c.

LHENG, C₁₀H₁₀N₂O₄, is a white fragrant deep-yellow powder, which is the powder of the seeds. It is used in dyeing red, rose-colour, and pink. It is used in large quantities in Russia. Harmaline yields a number of substitution products, such as a-Karkandine, cyanoharmaline, &c.

LELLENING, C₂₀H₂₂N₂O₄, a compound formed when salicine is acted on by dilute nitric acid. It contains the elements of sugar and hydrazide of salicyle. It crystallises in the form of yellow needles. When heated to 347° it forms a resinous insoluble substance.

HULLUSINE, C₁₀H₁₀N₂O₄, is a yellow powder, which is the powder of the seeds. It is used in dyeing red, rose-colour, and pink. It is used in large quantities in Russia. Harmaline yields a number of substitution products, such as a-Karkandine, cyanoharmaline, &c.

HYPERLURACIN, C₁₆H₁₄N₂O₄, discovered by Unger, and formed by burning on charcoal with hydrochloric acid, has been called chloro-phenol. It differs in composition from nitric acid by 1 equivalent of water and 2 of oxygen, hence its name. It is colourless, and crystallises in short rhombic prisms, and when heated, is resolved into hydrated cyanic acid, water, and carbon.

HUMALLINE, C₁₀H₁₂N₂O₆, a carbonyl hydrogen found in the mines of Idria. It colours sulphuric acid intensely blue. It is probably identical with succinisterine, a substance obtained from amber, and which has the same property of colouring oil of vitriol intensely blue.

HYRITHOXINE, C₁₂H₁₂O₂₂, discovered by Auber, and formed by burning on charcoal with hydrochloric acid, has been called chloro-phenol. It differs in composition from nitric acid by 1 equivalent of water and 2 of oxygen, hence its name. It is colourless, and crystallises in short rhombic prisms, and when heated, is resolved into hydrated cyanic acid, water, and carbon.

LACTAMINE, C₁₆H₁₄N₂O₄, is obtained by the action of lactic acid on ammonia. It is interesting as being identical in composition with the name of this substance, which is the real one, and is found in many sizes of crystals.

LACTAMINE, C₁₆H₁₄N₂O₄, is obtained by the action of lactic acid on ammonia. It is interesting as being identical in composition with the name of this substance, which is the real one, and is found in many sizes of crystals.

LEWISINE, C₁₆H₁₄N₂O₄, discovered by Unger, and formed by burning on charcoal with hydrochloric acid, has been called chloro-phenol. It differs in composition from nitric acid by 1 equivalent of water and 2 of oxygen, hence its name. It is colourless, and crystallises in short rhombic prisms, and when heated, is resolved into hydrated cyanic acid, water, and carbon.

LACTOUSINE, C₁₆H₁₄N₂O₄, is obtained by the action of lactic acid on ammonia. It is interesting as being identical in composition with the name of this substance, which is the real one, and is found in many sizes of crystals.

LACTOUSINE, C₁₆H₁₄N₂O₄, is obtained by the action of lactic acid on ammonia. It is interesting as being identical in composition with the name of this substance, which is the real one, and is found in many sizes of crystals.

LACTAMINE, C₁₆H₁₄N₂O₄, is obtained by the action of lactic acid on ammonia. It is interesting as being identical in composition with the name of this substance, which is the real one, and is found in many sizes of crystals.

LACTAMINE, C₁₆H₁₄N₂O₄, is obtained by the action of lactic acid on ammonia. It is interesting as being identical in composition with the name of this substance, which is the real one, and is found in many sizes of crystals.

covered by Schunck, to whom chemistry is greatly indebted for a knowledge of the compounds contained in the roots of Liriope.

Liriope is the name given to a substance possessing the properties of gum, and which is produced by simply exposing starch to a temperature of 300°. It has a brown colour and a sweet and aromatic smell, and is externally used instead of this substance in calico printing.

Lucido Acid, CO₂H₂O₄, an organic acid belonging to the lentic acid series, is a substance identical in composition with glycyrrhizic and alamine. It has the same relation to valeric acid that they have to formic and acetic acids. It forms crystalline scales, which are volatile, and when heated with potash they yield valeric acid, carbonic acid, and hydrogen. The latter substance has been detected in the liver of the calf as a natural product. It is also found among the products of the putrefaction of fibrous and albuminous substances.

Lucidol, CO₂H, is one of the compounds found in the least volatile portions of the basic oil of castor. It is also formed when quinine, cinchonine, strychnine, or thialine are heated with potash. It is a liquid with a disagreeable smell, and boils at the temperature of 460°. It neutralises acids, and forms with them a crystalline salt.

Lycocysteine [Harmaline].

Lycoperone, CO₂H₂O₆, is a variety of starch found in the Lichen Islandicum, or Iceland moss. It is colourless and tasteless, swelling up into a jelly-like mass in cold water, and dissolving in both water and alcohol on being boiled with a bituminous kind. It is not coloured by boiling with iodine, but the jelly is. It is converted into sugar by dilution and boiling sulphuric acid.

Limonin, CO₂H₂O₅, is a bitter crystalline substance formed from limes and oranges. It closely resembles Chineine, the bitter principle of the Cinchonaphthalein. It contains 2 atoms less water.

Lilac. [Glyceeryl.]

Lophine, CO₂H₂, is one of the bases derived from the oil of bois de rose. It is formed when hydrobromide (CO₂H₂Br₃) is distilled. Ammonia is given off, and lophine is left undissolved. It is soluble in alcohol with acids, and precipitated again by ammonia. It occurs in the form of fine silky crystals, and acts towards acids in the manner of a base. By the action of nitric acid it yields a yellow crystalline compound called trigonocephale.

Luteolin is a non-aestivated coloring principle found in the wood (Isatis tinctoria). It is volatile and crystallisable.

Luteolide, and Malamino Acid, are synonyms of Asparagine and Aspartic acid. [Asparagine - Chemistry, S. 1.]

Melampyrine is a crystallised non-aestivated substance obtained from the cow-wheat, Melampyrum nemorosum. It is a white powder like desiccated sugar.

Melasine Acid, CO₂H₂O₄, is formed from cane sugar by the action of heat and alkalis. It has a very dark colour, and when thrown down by hydrochloric acid appears as a black flocculent deposit.

Melosin Acid, CO₂H₂O₄, is one of the substances yielded by wax. According to Brodie, when the hydrated oxide of melosine or melasine is heated with lime and potash, it yields hydrogen gas and melasine of the base. When the acid is separated, it presents itself as a crystalline wax-like substance, melting at 192°.

Melrose. [Manson - Chemistry, S. 1.]

Mesalin, CO₂H₂O₄, a negative radical found in myricine, a substance which forms about four-fifths of bees' wax. It consists of the hydrated oxide of melasine combined with palmitic acid. The palmitic acid is easily separated from the hydrated oxide of melasine by saponification. The latter is a true alcohol, and, like common alcohol, yields a carbolic acid resembling olefiant gas. Its composition is CO₂H₂O₄. It is identical with the acid volatile in scotch whiskey. This compound is very interesting, as it has been shown by Brodie to possess the same relations, and to form a series of compounds homologous with those of ethylene and methylene, the latter being a carbonyl alcohol.

Mesembrine, CO₂H₂O₄, is a white fusible crystallisable alkaloid, forming salts with the acids found in the seeds of the Mespilus Physalis. It is also known as Coccus Acid.

Mестиллин, CO₂H₂O₄, is obtained from the distillation of acetone with forming sulphuric acid. Thus, 3 mol. of acetone = (3(CO₂H₂O₄), yield 6H₂O and mesityle. The atoms of hydrogen may be substituted by chlorine, bromine, and nitrons acid.

Mesilomine Acid, CO₂H₂O₄OH₂, is an acid described by Gottlieb and obtained from the action of nitric acid on echinacea citric acid. It forms minute crystals, sparingly soluble in water.

Methionine Acid, S₂C₂H₂O₅, this acid with Ethylic, isethionic, and althionic acid is formed by the action of sulphuric acid on ethylene and alcohol.

Méthyl-urea. [Aniline.]

Méthylidoethymalylum. [Amylne.]

Méthyllethylmalylum. [Amylne.]

Micinomonic Acid. The tannic acid produced from catech in possessing the composition different from that of the tannic acid from oak bark, and Berzelius proposed calling the one minomonic acid, from Mizoma, and the other quercinonic acid, from Quercus, the name of the oak.

Micrargine. [Méthylène.]

Myronispermine. Balsam of Peru, according to Richter, contains two oils, myroxyline, which is insoluble in alcohol and myrinospermsine, which is soluble in that liquid. The latter substance when treated with an alcoholic solution of potassium yields a resin resembling cinnamonic acid, which is called myricpic acid.

Myristic Acid, CO₂H₂O₄ + H₂O, is a crystalline fatty acid found in the seeds of Myristica scoirba, the common nutmeg. Combined with the oxide of hylipie, it forms the most fragrant of essences, that known as natural musk, the oxide of ethyle a myristate which is an oily liquid.

Naphthalin, CO₂H₂, or CO₂H₃, is found in all kinds of tar, but especially in coal tar. It is easily obtained by redistilling this substance, when it occurs in the form of a solid state. It may be then purified by sublimation and crystallised from hot alcohol. It is colourless and volatile, forming large tabular transparent crystals, with a peculiar smell and an acid taste. It is volatilised like camphor by exposure to the atmosphere, and is a constituent of 414°. It forms with bromine and chloride a large number of compounds by substitution, and is acted on in the same way by sulphuric and nitric acids. These compounds have been studied with great diligence and singular accuracy by Laurent, who has found on their his great law of substitutions, which has been one of the most remarkable aids to the development of modern organic chemistry. [Chlorinaphthale.]

The compounds of chlorine and bromine with naphthaline are very numerous, and have many of them been carefully described. The whole number of these two elements with naphthaline amounts to the large number of 1040. In the same manner sulphuric and nitric acids are found to act on naphthaline, and to give a long series of compounds highly interesting to the chemist, but which have not yet been fully studied. The following are a few examples of these compounds:

Hypomorphonaphthalic acid. CO₂H₂S₄O₄ + H₂O.

Hypomorphonaphthalic acid. CO₂H₂S₄O₄.

Sulphonaphthale. CO₂H₂S₄O₇.

Sulphonaphthale. CO₂H₂S₄O₇.

Nitronaphthale. CO₂H₂N₄O₇.

Thionaphthallic Acid. CO₂H₂N₄O₇ + H₂O.

Nitronaphthalene. CO₂H₂N₄O₉.

Nitronaphthalene. CO₂H₂N₄O₉.

Odonine. [Picoline.]

Cénaétique Acid, CO₂H₂O₄ + H₂O, is found in wines in combination with oxide of ethyle, forming an ether, which is one of the most important of the ethers of wines. It is also found in the spirit of fermented grains. In order to obtain the acid, the ether is decomposed by caustic potash, and the manesate of potash thus formed is distilled with dilute sulphuric acid. The acid thus obtained is a semi-liquid substance insoluble in water, but soluble in alcohol and ether. The manesate of oxide of ethyle, manesane ether, is a colourless liquid, having the well-known smell of wine, and producing a stupefying effect. This ether has been shown by Mulder to be only one of many ethers which give the long series of compounds known to wine. (Mulder's Chemistry of Wine.)

Cénaétique Acid, CO₂H₄, is known by some of its compounds. Hydrated Oxide of Ebanyle - Ebanyle - Ebanyle - Ebanyle - Ebanyle + H₂O, the latter is the alcohol of anamathine acid, and is obtained from castor oil. Anamathine Acid, CO₂H₂O₄ + H₂O,
is an oily acid, and yields fatty salts. The enanthuates of the oxides of ethyle and methyl are fragrant compounds.

Quercitrine. [Quercitine.]

Oxalic acid, CO\(_2\)H, is obtained from the phellandrene of amber by the loss of one equivalent of ammonia and four of water. It is a pale yellow powder, which, when boiled with water, yields oxalic acid and phellandrene.

Oxalyl acid, CO\(_2\)H\(_2\)O, is formed from the decomposition of Oxychelic acid, one of the compounds contained in opium. This acid forms soluble and crystallisable salts, with the oxides of the metals and oxide of ethyle. The latter is orange.

Oxaline, CO\(_2\)N H\(_2\) O\(_3\), is a crystalline compound found in company with narcotine and other compounds to opium.

Oxaline, CO\(_2\)H\(_2\)O, is formed by the action of nitric acid on narcotine. It crystallises in fine needles, which are soluble in ether and alcohol, and become a deep blue when brought in contact with sulphuric acid.

Orthine. [Orthinic Acid.]

Ortholine. [Athlanticine.]

Orthic Acid, O O\(_3\) N H\(_2\), is one of the products of the action of heat on oxalate of ammonia. This acid forms soluble and crystallisable salts, with lime, baryta, ammonia, and oxide of silver.

Palmatic Acid. [Cetyl.]

Paraffine, CO\(_2\)H\(_2\) O\(_3\), a crystalline base discovered by Meck in 1803.

Paraffin acid, CO\(_2\)H NO\(_3\), is formed when mellitate of uric acid is heated in a retort to about 330°. It is accompanied by another body called Ethyric Acid. Paraffin acid is a solid yellowish oil, which, when boiled with water, changes into a bismutinate of ammonia.

Paraphenylene = Atracene, CO\(_2\)H\(_2\), is a substance polymeric with naphthalene, and also found in coal tar. It melts at 366° and distils at 392°, crystallising in foliated plates. It forms with nitric acid a series of compounds, in which oxygen is substituted for hydrogen. These compounds are again capable of uniting with hyponitrous acid. As with the compounds of naphthalene we are indebted for all that is known of these to the researches of Laurent.

Paraline Acid, CO\(_2\)H\(_2\), O\(_3\), one of the substances produced in the various dyeing lychens of commerce. It is found in company with lecanoric acid.

Parietine = Bhrabarine = Parietine Acid = Chrysophane Acid, CO\(_2\)H\(_2\) O\(_3\). This substance, which was first found in rhubarb and has the above names, is also found in the Parmelia paretina. [Chrysophane Acid.]

Pelargonion Acid, CO\(_2\)H\(_2\) O\(_3\) H, is found in the oil of Pelargonion roseum. It is an acid oily liquid, with a rancid smell, and resembles aloe-ether in both its chemistry and constitution. It passes on heating through a volatile, tasteless, colourless liquid, CO\(_2\)H\(_2\) O\(_3\) H, which is an oily liquid of a very peculiar smell. It is stated by Frankland that whiskey owes its peculiar flavour to this compound. It is manufactured for the purpose of giving new whiskey the flavour of old. It is probable this acid is formed from sugars, as all oily acids are found to be.

Phenec, CO\(_2\)H, the hypothetical base of carboxic acid, which according to Laurent is an Hydrated oxide of Phenyle, CO\(_2\)H\(_3\) H O\(_3\). Laurent has succeeded in obtaining with this radical phenyle a series of compounds resembling those of indigo, salicide, and other bodies.

Phelline is a non-grossed compound, crystallising in silver scales and of a bitter taste, obtained from various species of Philea.

Phlebotine. [Phlebintin.]

Phlebinedine. [Phlemin.]

Phlorin, CO\(_2\)H\(_2\) O\(_3\), is a substance closely resembling uric acid. It is obtained from the roots of the apple, pear, plum, &c., and is extracted in the same way as salicine. It crystallises in the form of small scales, which are soluble in hot water and alcohol.

It is a very bitter and powerfully sebific. When boiled with water, it gives a resinous substance called phlorotin, CO\(_2\)H\(_2\) O\(_3\) and grape sugar.

If phlorizin moist be exposed to atmospheric air and ammonia it forms a deep red substance, soluble in ammonia, and which is precipitated from the solution by the addition of the same quantity of ammonia as eight equivalents of oxygen and two of ammonia. This is phlorizin.

Phlobatine, CO\(_2\)H\(_2\) N O\(_3\), is formed from phlobatic acid by ammonia.

Phlobatic acid, CO\(_2\)H\(_2\) O\(_3\), N H\(_2\) O, obtained from the action of nitric acid on chlorides of phlobatine.

PICOLINE, C\(_4\)H\(_7\) N, is a volatile oily base, isomeric with aniline, and found in coal tar. It has very powerful basic properties, and forms the same substance as the odorous described by Unverdorben.

Picolinic Acid = Carboxylic Acid = Nitropropionic Acid = Nitrophenolic Acid, C\(_4\)H\(_7\) N O\(_3\) + H O, formed by the action of nitric acid on aniline, indigo, salicine, salileye, salicylic acid, hydrate of phylene, common silk, and other substances. However obtained it assumes a crystalline form, and is of a pale yellow or white. It has a very bitter taste, and is said to take effect for alleviating bitter beer. It is fusible and volatile, readily uniting with bases; its salts crystallise and explode when heated.

Picrolaxine, a bitter principle obtained from the seeds of M. coccuta (Coccuta Indica). It forms white crystals on evaporation, and appears to be a vegetable base containing nitrogen.

Pine=Picric, C\(_4\)H\(_7\) N O\(_3\), is yielded by the distillation of the product obtained by acting on oil of bitter almonds with sulphuret of ammonia. By the action of nitric acid it is converted into trinitropicryl C\(_4\)H\(_7\)NO\(_3\) + N O\(_3\) which is a yellow crystalline powder.

Pine Apple Flavor. [Butyl.]

Pothacrine, a crystalline compound found in Bengal opium.

Pophene, C\(_4\)H\(_7\) O, a compound homologous with acetone. It is formed when propylate of baryta is exposed to heat. When oxidised it yields propylic acid. It is a volatile oily fragrant liquid, which forms a crystalline acid.

Ponyle, CO\(_2\)H, a compound hypothetical radical. Some of its compounds are known, but not its ether or its alcohol. Propylic acid, C\(_4\)H\(_7\) O + H O, is however well known, and has this radical for its base. This acid is next above acetic acid in arrangement, and is procured by heating the cyanide of ethyle with a solution of potash in alcohol. Propylate of potash is thus obtained, which must be distilled with sulphuric acid, when propylic acid passes over. It is an oily acid, and its salts have something of a fatty character.

Praherine. [Pareine.]

Rhodosertine, C\(_4\)H\(_7\) O\(_3\), an acid found in Jalap. It has the property of striking a fine red colour with sulphuric acid. When combined with bases, it takes up an equivalent of water, and is then called hydrachrodosertine. When acted on by hydrochloric acid, it is resolved into glucose and an oily substance called rhodoterine. In this respect rhodo-

Sertine resembles salicine and phloridzin.

Romane, C\(_4\)H\(_7\) O\(_3\), a yellow crystalline acid found in madder (Rubia tinctorum).

Rubin acid, a red acid obtained from catechines, and tanninaceous acid. [Catechene.]

Rubin acid, a red acid obtained from catechines, and tanninaceous acid. [Catechene.]

Rubine, O\(_3\), an acid found in Jalap. It has the property of striking a fine red colour with sulphuric acid. When combined with bases, it takes up an equivalent of water, and is then called hydrachrodosertine. When acted on by hydrochloric acid, it is resolved into glucose and an oily substance called rhodoterine. In this respect rhodo-

Sertine resembles salicine and phloridzin.

Sonne, an active principle found in the Saponaria officinalis. Although this plant is apparently inactive, this principle is a powerful stimulant, and has a sweet and acid taste. It is soluble in water, and when agitated it froths like soap. Saponaria was formerly used as a detergent.

Sonnolene, a compound formed by the action of seleni-

Selenuretted hydrogen on asdialdehydeammonia.

Sorbarose, a sweet principle, obtained from the Polygala Senega. It acts as a sedative.

Simpoline, C\(_4\)H\(_7\) N O\(_3\), a base obtained from oil of mustard by the action of the moist hydrated oxide of lead.

Simpolamine, C\(_4\)H\(_7\) N O\(_3\), a base obtained by acting on Thio-

Sipatline, C\(_4\)H\(_7\) N O\(_3\), by any oxide of lead or mercury when the latter loses all its sulphur, and a portion of its
hydrogen, and sianamine is left. It forms definite compounds with chlorides of mercury and platinum.

**Synaptase**. C₄H₈O₈, one of the three solids which, according to Kane, exist in combination in addition to Erythroline, which is a red fluid. The other solids are Aosolitmine and Erythroline.

**Styline**, C₄H₈O₈, one of the products of the decomposition of the compounds of benzoyl. It is formed from the hydrol of C₄H₈O₈ and is a permitted further, when it is heated, gives off sulphuretted hydrogen, and at last distills over, in nearly scales, stilbene. It forms a compound with chlorine when this gas is passed through melted stilbene. Bromine also combines with stilbene, forming bromide of stilbene, the substitution of nitric acid, nitrosidobenzine, nitro-stilbene, and nitro-sulphuric acid.

**Synaptoine**, C₄H₈O₂, is a substance procured from liquid starch, by distillation with carbonate of soda. At the same time it yields ammonium of soda and emulsin, C₄H₈O. It is probable from this fact that styrole and cinnacone are the same substance. Styracine may be regarded as a compound of cinnamic acid, C₄H₈O₂, with the oxide of a compound radical, C₄H₈, which is called styrole. If styracine be heated with a solution of potash, a cinnamic of potash is left, and a hydrated oxide of styrole distills over. This substance exists in two forms, as a solid and as a liquid, and has been described under the name of styrone.

**Syrhythm**, C₄H₈O₂, the hypothetical radical of sucrine acid, and is not to be confounded with the well-known syrhythm of the formula C₄H₈O₂ + H₂O.

**Sianamine.** [Jamardine.]

**Synaptase** = *Emulrin*. The white part of both sweet and bitter almonds is principally composed of a peculiar matter, which, in the water, in which it has been called syrnaptase by M. Robiquet. It appears to be identical with a substance desribed by Liebig and Wöhler, and called by them emulrin. Robiquet prepared synaptase by submitting sweet almonds, from which all the oil had been expressed, to maceration for two hours, and then subjecting them to pressure gradually increased. The filtered liquid holds vegetable albumen in solution which may be thrown down by acetic acid, also gum which may be precipitated with acetate of lead. The liquid now contains acetate of lead, acetic acid, sugars, tannin, and a small quantity of lead may be left over, sulphuretted hydrogen, and the synaptase by alcohol. The synaptase should be washed with alcohol, and dried in evers over sulphuric acid. The dry synaptase is a yellowish white opaque horny mass, which is very soluble in cold water. Iodine produces in the solution a rose color. The synaptase soon decomposes in solution, deposits a white precipitate, and acquires a mouldy odor. It coagulates at 140°, like albumen. It contains asote and produces ammonium. The following are the results of two analyses of this substance by Dr. R. D. Thomson, and Mr. Richardson.

The action of syrnaptase on the amygdalin of the almond is very singular, and throws light on the way in which the oil of bitter almonds is formed in some of the seeds of the almond-tree. "On mixing a solution of 10 parts of amygdalin in 100 parts of water, a particular decomposition immediately takes place; the mixture becomes opaqueless without any turbulence; a certain density; sequence of bitter almonds, and gives on distillation hydrocyanic acid and hyduret of benzoyl with the vapour of water. The residue is rendered turbid by coagulated synaptase, and on continuing the evaporation, a very sweet liquid is obtained, which contains crystallizable sugar. After depositing the sugar by fermentation, a fixed acid remains in the residue. The quantity of sugar obtained is more considerable than what the elements of the amygdalin could produce; it would appear, therefore, that the substance of which the amygdalin is composed is capable of undergoing a decomposition different from its formation. The decomposition is not complete unless the amygdalin and synaptase are dissolved in a proper quantity of water; if it is insufficient to dissolve the hyduret of benzoyl liberated, a corresponding quantity of amygdalin remains insoluble. (Taub.) The two constituents of the bitter almond are the fixed oil, which is separated by expression, and the synaptase and amygdalin, the two last in such a condition that they cannot re-act upon each other. When the almond cake is treated with boiling alcohol, the amygdalin is dissolved out, and the synaptase coagulated. When the cake is moistened with water, the odours of hydrocyanic acid, and of the essence, are immediately perceived, but the cake must be diffused through a certain quantity of water, in order that the mutual action of the synaptase and amygdalin may be complete, and that the whole of the last may disappear. In preparing the distilled water of bitter almonds of pharmacy, M. Liebig recommends that a mixture of 1 part of liquid extract of inkomagne, and 4 parts water, be left to itself for twenty-four hours before submitting it to distillation. One atom of amygdalin contains the elements of (Liebig):—

1 equiv. of hydrocyanic acid   C₄H₈N₈O₄
2 equiv. of hydroxet of benzoyl C₄H₈O₄
equiv. of sugar               C₄H₈O₈
2 equiv. of formic acid       C₄H₈O₄
7 equiv. of water             C₄H₈O₈

I equivalent of amygdalin C₄H₈O₄N₈

One hundred parts of amygdalin are said to yield 47 parts of the crude essence of bitter almonds, and these 47 parts to contain 59 parts of free hydrocyanic acid. The last acid is not indicated by nitrate of silver added to a solution of the crude essence in water, owing to the presence of the oil; to obtain a precipitate of cyanide of silver, ammonia-nitrate of silver must be used, and the ammonia saturated with nitric acid, after the lapse of some time." (Graham's Chemistry.)

**Syrmaptase** has hitiered a principle, found in the common lilac (Synrhga vulgaris).

**Tannactine**, a non-oxitised vegetable principle, obtained from the Tannacostum vulgar, the common tansy. It is a brownish yellow crystalline compound, obtained from the Tongphoriae semen, a poisonous ree in Madagascar.

**Tartaric Acid**, C₄H₆O₆ + 2 H₂O, and Tartaric Acid, C₄H₆O₆ + 2 H₂O, two acids obtained from tartaric acid. By long contact with water their salts are converted into tartarates and tartaric acid.

**Tartaninamine**, C₄H₈O₄S₂, a compound described by Anderson. It is obtained from nuxomine by the action of nitric acid of moderate strength. It forms small white crystals, which are sparingly soluble, and which present a crimson red colour when heated with sulphuric acid.

**Tobramyammon**, C₄H₈N₈O₄M⁺, a compound described by Tropman. It is obtained from nuxomine by the action of nitric acid of moderate strength. It forms small white crystals, which are sparingly soluble, and which present a crimson red colour when heated with sulphuric acid.

**Tobramyammon**, C₄H₈N₈O₄S⁺. When ammonia is added to the pure oil of mustard, C₄H₈N₈S⁺, this substance is formed. It is crystalline, acts as a powerful base, and yields a variety of interesting compounds. [See below.]

**Toluene**, C₄H₈N₈O₄M⁺. When ammonia is added to the pure oil of mustard, C₄H₈N₈S⁺, this substance is formed. It is crystalline, acts as a powerful base, and yields a variety of interesting compounds. [See below.]

**Toloxalic acid**, C₄H₈O₄S⁺, corresponds with hemic acid.

**Uryase** [fuslyx].

**Ustyl**, C₄N₈O₂, is the hypothetical base of the various compounds obtained from uric or lithic acid. This base is also known by the name of Cymozams acid, as it contains the elements of 2 equivalents of oxalyl, and 2 of cyanogen.

The following table will show the relation of this substance to the various compounds derived from uric acid:—

**Valerolanic acid**, C₄H₈O₄ + H₂O, is classified in nature, in 4 parts of valerian, obtained from the Valeriana officinal. It is obtained from cat in oil, and sperm oil combined with the oxide of lime. It also occurs in various fats and oils from the animal kingdom, and in the seeds of the guilder rose (Fibarium Opulae). **Valerate of the oxide of Ribile** is a fragrant ether, and is
found in plants, giving a peculiar scent to those which possess it. It combines with various other bases. The compounds of valerian, as far as they are known, are homologous with those of methyl, ethyl, formyl, and acetylic.

**Xylochin, C\textsubscript{6}H\textsubscript{10}O\textsubscript{5}NO.** When potato starch is rubbed up with strong nitric acid, the starch is dissolved, and a yellow liquid is produced from which water precipitates the compound called xylochin. It resembles in some of its properties the homologous gum, but it contains so large a quantity of nitric acid that it is explosive.

The following works may be consulted on the subject of the present state of Organic Chemistry:—Gregory’s Handbook of Organic Chemistry; M. de Chenu, Elements of Chemistry; Chem. & Met. Cyclopedia, edited by Graham; and Lechmann’s Physiological Chemistry, translated by Day for the Cavendish Society; Gmelin’s Handbook of Chemistry, translated by Watts for the Cavendish Society; Bowman’s Medical Chemistry; Turner’s Elements of Chemistry, edited by Liebig; and Graham’s Elements of Chemistry.

**CHERT,** a variety of quartz being a kind of granular Chaledony. It is a transition from the softer forms of Quartz to Hornstone. [Aeol.]

**Chem. & Met. Cyclopedia.**

**CHIGWELL.** [Essex.]

**CHILDREN, JOHN GEORGE,** was born on the 18th of May, 1777, at Ferox Hall, Tonbridge. From the Grammar school at Tonbridge, he proceeded to Christ Church, Oxford, in 1794, entered Queen’s College, Cambridge, as a fellow-commoner.

He studied with a view to the church, but the early death of his wife led him to travel in the south of Europe and in the United States, from whence he returned to devote himself to chemical pursuits.

While studying mineralogy, chemistry, and galvanism, he made the acquaintance of Davy, Wollaston, and other leading men of science. In 1807 he was elected a Fellow of the Royal Society. In the following year he contributed a paper to the ‘Philosophical Transactions,’ on some experiments performed with a view to ascertain the most advantageous method of constructing a voltaic apparatus, for the purposes of chemical research, in which he determined the effect of unequal paper, which he covered with the guano, the contents of which vary from four to five feet in height; and the walls of the island, which present a series of many, the nearest of which is at a distance of eight miles.

**Chinese, the**

**Chinese.** The British and French forces continue to hold possession of Canton. Commissioner Yeh was captured on the 5th of January, 1859, and also the Tartar general.

**CHINCHAS.** Island of Pique, on the coast of Peru, lies between 13° and 14° S. lat., 76° and 77° W. long. They are naturally bare rocks, without a sign of vegetation of any sort, but they have obtained great remarks, the rocky inequalities of the original surface having been filled up and covered with the guano, the contents of which vary from fifty to one hundred feet in height; the sides of the island, which is about three miles in width, are separated by channels from one mile to two miles broad. In their general form they are all alike. On the eastern side they present a perpendicular wall of rock, from the top of which Descanso, a Gentleman, in 1815 by a paper, published also in the ‘Philosophical Transactions,’ ‘an account of some experiments with a large voltaic battery,’ in which a further series of singularly interesting results was described, among them the conversion of iron into steel by union with nickel, under the same conditions, as the voltaic apparatus.

Between the dates of these papers Mr. Children travelled in Spain, and visited the quicksilver mines of Aímadén, then but little known in England. In 1816 he was appointed one of the professors at the University of London, and at that time was elected secretary of the Royal Society, and resigning the following year on account of ill health, was re-elected in 1830, and retained the office for seven years. In 1839, on the death of his third wife, Mr. Children resigned his post at the British Museum. He died on the first day of 1852.

**China.** In the previous Supplement, under the head **China,** an account is given of the last war between Great Britain and China, from its commencement in 1840 to its termination in 1842. In this Supplement, as well as of the events which preceded the war, and the treaties by which it was followed. The forts in the Canton river were attacked and taken, and a large number of war-junks burned. Lord Elgin was sent out as Her Majesty’s commissioner, with a fleet and troops, for the purpose of entering into negotiations with the Emperor of China. Meanwhile the British had broken out in Hindostan, most of the troops went from England were required to assist in quelling it, and the quarrel with the Chinese remained unsettled. As however the dispute was confined to Canton and the authorities there, especially the French, had resolved to attack the forts of Canton. This operation was successfully performed in the morning of the 29th of December, 1857, when the principal batteries were taken, and the greater part of the defences of the city were taken possession of. The assault was conducted by Major-General Van Straussen, commander-in-chief of the British troops in China, with about 4000 men, assisted by Rear-Admiral Sir Michael Seymour, commander of the British naval forces, and by Rear-Admiral Sir Rigaud de Genouilly, commander of the French naval forces, with about 1500 men. The British and French forces continue to hold possession of Canton. Commissioner Yeh was captured on the 5th of January, 1859, and also the Tartar general.
longer than the calyx, the filaments densely-bearded. It is a native of Brazil, in woods at Almeida and Serradas, on the mountains of Bahia, and at the port of St. Catherine.

C. odorata, Sweet-Scented Snow-Berry, has ovate acuminate leaves; stipules very broad, short, each ending in a short point; racemes panicked; corolla not quite three times longer than the calyx teeth. It is a native of Brazil in woods, French Guyana, Trinidad, Perú, Cuba, and on the Spanish Main.

In 1819 Mr. Clark undertook to complete the Thames and Medway Canal, a work which had been stopped for want of capital, and under his direction it was finished some years afterwards; and the great tunnel through the Furdybore hills, through which the bridge was passed, was the suspension-bridge over the Thames at Hammersmith, which was commenced in 1824 and finished in 1827. It is chiefly remarkable for the small deflection of the chains between the chord-line or points of suspension. The suspension-bridge at Marlow was also designed by Mr. Clark, and he was employed by the late Duke of Norfolk to build one over the Arun.

Mr. Clark was however best known by the suspension-bridge which he constructed across the Danube at Pest. It was begun in 1859 and finished in 1849, at a cost of 622,000 L. At times the bursting of dams and the pressure from accumulated ice in the winter threatened a total stoppage of the works, but all obstacles were overcome by the energy of Mr. Clark. He was a remarkable monument of his genius and skill.

Mr. Clark was elected a Fellow of the Royal Society in 1837; he was a Fellow also of the Astronomical Society, and a member of the Institution of Civil Engineers. He died September 26th, 1857.

CLARKSON, THOMAS, was born March 26, 1790, at Wisbeach, Cambridgeshire, where his father, who was a clergyman, was master of the free grammar school. He was at first intended for the church, but his father had, when he was sent to St. Paul's School, London, and thence to St. John's College, Cambridge, where he gained the first prize for a Latin dissertation proposed for the middle bachelors. In the following year, 1755, the Vice-Chancellor of the University anointed another essay on the same subject, 'Anne liceat invitio in servitutem dare?' ('Is it right to make slaves of others against their will?'). The prize was awarded to Clarkson for his essay, which was read with great applause in the Senate House, in June, 1786. He had used much industry in collecting materials for this dissertation, and had become greatly excited by what he had read of the miseries to which the slaves were subjected in the carrying on of the trade. He resolved to use all his efforts to get its suppression. He was appointed an assistant of the church or chapel of ease. The ministers of these districts are usually denominates incumbents, not being parsons and vicars, properly so-called. The Church Building Commission, although by the original Act limited to ten years, was from time to time extended; and the Church Building Commissions, which have been recently transferred to the Ecclesiastical Commissioners.

CINCHOVATINA. [CHEMISTRY, S. 1.]

CHINMADRON, a genus of plants referred to Von Martius's doubtful order Cannadina. This genus has been separated from Canadina, which is well represented by C. alba, a common West Indian aromatic shrub, with everlasting coriaceous obovate alternate stalked leaves, no stipules, and coryms of purple flowers. C. alba is often called Wild Cinnamon in the West Indies, on account of its warm aromatic fragrant properties. There is but one other species of Canadina. Cinnamomadron has but one species, C. axillare. It is a Brazilian tree with aromatic properties. Its bark is used as a tonic and stimulant. It is administered in low doses and relaxed sore throat.

CINNAMON. [Sun-Brass.]

CLAIM IN CHANCERY. [Equity, S. 2.]

CHALAM. [Barbery.]

CLARK, WILLIAM TIERNEY, a civil engineer, was born at Sion House, Somersetshire, August 23, 1783. He was apprenticed when very young to a millwright in Bristol, and followed the trade for several years in that city and at Coventry. He removed to London, and entered the service of the late Mr. Rennie as draughtsman; and held the employment till 1811, when he was appointed engineer of the West Midlands Waterworks. The establishment was at that time on a very small scale—an engine of twenty-horse power supplying the neighbouring hamlets from an insufficient reservoir, yielding no profit to the company. But under Mr. Clark's advice the works were enlarged, and he spared no exertion to render them complete and effectual, until at last there were three pumping-engines of the aggregate power of 243 horses, and reservoirs capacious enough to contain from 30 to 40 million gallons, and producing an annual rental of nearly 70,000 L. This post he retained for the remainder of his life.

But the exertions of Clarkson and his supporters, who had now become numerous, did not terminate with the suppression of the trade in slaves. The struggle was afterwards continued during another twenty years for the total abolition
CLAY, HENRY, was born in Hanover county, Virginia, April 12, 1777. He was the seventh son of a clergyman, who died when Henry was very young, leaving his widow and only four of her seven children. He was brought up on the common school education. Henry obtained a situation as copying clerk in the chancery court of Richmond. Here he probably received a certain amount of initiation in legal proceedings, although he was not of age. When he formally commenced the study of the law, he was then only twenty admitted to practize at the bar. The tide of migration was then setting strongly westward, and the young advocate thought that the fertile valleys of the west offered a fairer field for his exertions. He consequently removed to Lexington in Kentucky, and there, in October 1799, he fairly commenced his legal career. As an advocate he quickly achieved a marked success. Young Clay, it was soon seen, not only possessed great natural ability and doubled its value by constant diligence, but had the more marketable talent of knowing how to manage a jury. Yet though he found himself on the road to fortune, his ambition was directed rather towards political than professional success. In 1802 he again put forth his claim to the seat of the state for the state of Kentucky. Clay, soon after, obtained an appointment as a clerk in the General Assembly of Kentucky, of which he was chosen speaker; an office he held till he was in 1811 re-elected for an unexpired term of three years. His political career was now fairly begun, and for nearly fifty years his life may be said to have been devoted to the service of his country. His first election to Congress was in 1806, but it was only for the remaining portion of a term; and in 1807 he was again elected to the General Assembly of Kentucky, of which he was chosen speaker; an office he held till he was in 1809 elected for an unexpired term of two years to the Senate of the United States. In 1811 he was sent as a representative to Congress, and on the meeting of the House of Representatives he received the very remarkable honor of being elected speaker, though he was now for the first time a member of the house. But his speeches in the Senate, and his conduct as speaker of the Kentucky Assembly, had established his reputation; and so well satisfied were the people with his choice, that he was re-elected for re-election to that body in 1814. In both his previous efforts he had taken a prominent part in the great questions of the day, but especially distinguished himself by his earnest denunciations of the English claims to right of search and other maritime privileges, and by his active and unceasing efforts to aid the suffering of the people in the war with England, so during its continuance he remained one of its strongest advocates. He was in 1814 appointed, avowedly in consequence of the leading part he had taken in the discussions on the war, one of the commissioners to negotiate the treaty of peace. On his return to America he was at once re-elected to Congress.

He now directed his energies to home legislation; but when the question of South American independence was before the Senate, he was unexpected, Clay was already promulgating his favorite idea of the emancipation of every species of European antimony from the American continent. While engaged in a decided course of political activity, he continued to maintain the same liberal policy, and there were two great measures which specially occupied his mind. One was the establishment of a national system of internal improvements, which the president opposed as unconstitutional, but which Clay successfully vindicated from that objection; and a re-establishment of a national bank. Both of these measures were carried, and the successful issue of his exertions placed Clay in the estimation of a large portion of his countrymen in the very first rank of American statesmen. He was now looked to by many as the probable heir of the presidency, and it was well understood that he himself coveted that elevated post. That he might be in a better position to bear the increased expenditure its acceptance would necessarily involve, he resigned in 1819 his seat in Congress, and returned to the active pursuit of his profession, in which he promptly regained a highly lucrative practice. But when the conventions began to consider the claims of the candidates for the presidency, it was apparent that Clay would not be chosen; his name was soon withdrawn. With this he went to the House of Representatives, by whom he was immediately restored to his place as speaker. Three candidates went to the vote for the presidency, but as neither could obtain the absolute majority required by law, the election was again placed to the House; and Clay, because of his influence in favor of Adams, was chosen; and in return appointed Clay secretary of state. This office he held until 1827, and during his occupancy of it discharged its duties with great ability.

On the election of General Jackson in 1829, Clay retired for awhile into private life, but in 1831 he was elected to the United States Senate. In 1833 Clay was again an unsuccessful candidate for the presidency. He had now to consider that the subject of his protracted and arduous career was re-opened, and the country was agitated from end to end. South and north were almost in open conflict. At length Clay brought forward his 'Compromise Bill;' it was accepted by both parties, and modified protection to national interests became the established law of the United States. His subsequent tour through the middle and eastern states was a continued triumph. Passed over at the presidential election of 1836, at that of 1839 his claims were more strongly urged. Clay had put forth his candidature, and the subject was re-opened, and the country was agitated from end to end. At the presidential election of 1844, the great man was again united. The events of 1828 had been a great shock to the Democratic party, and Clay was elected. Clay remained a member of the senate till 1842, when, finding that his strength was insufficient to sustain him in his arduous task, he withdrew, and the other side of the chamber and the office of Speaker were taken up by Polk. But the time was now approaching when Congress would have to consider the question of the nullification of the act of 1832, and the necessity for such an act, which would be a great blow to the cotton interests of the United States, and a great shock to the southern states. Clay was elected in 1849, when he was again returned to the Senate. To him was due the famous slavery 'Compromise Act' of 1850, which for a brief space quieted the bitter strife which the question of slavery had so long agitated in the country; and Clay lived long enough to perceive that as a permanent measure his project was a failure. He had laboured beyond his strength in an effort to establish the supremacy of the union in the South, and that union was longed for rest. But his was not to be a rest on earth. He resigned his office as senator, but before the day named for his resignation to take effect, he had ceased to live. He died June 29, 1852, aged 76. Henry Clay was undoubtedly a man of powerful intellect, but he will hardly retain the rank which his contemporaries too readily assigned him.
was wanting in comprehensiveness. His views were at best too strictly national, and, as in the case of the protective tariff, and in his general foreign policy, he too readily took for granted that what seemed to give an advantage to his countrymen was really for their benefit in the large view of the world.

CLINKSTONE, a grayish blue rock, consisting principally of Felispar. It passes gradually into gray basalt, but is distinguished from that rock by its lower specific gravity. When struck with a hammer it rings like iron. It is frequent in various localities.

CLINTON, HENRY FYNES, was born January 14, 1781, at Gamston in Nottinghamshire. He was the eldest son of the Rev. Charles Fynes Clinton, D.D., prebendary of Wem, chaplain of St. Mary's, and son of the 1st Viscount Clinton, and was descended in direct line from Henry, second earl of Lincoln. The family name was Fynes till his father obtained a royal licence, April 26, 1821, to resume the ancient family name of Clinton.

Mr. Clinton was educated at Southwell School, Nottinghamshire, where he remained from 1789 till 1796, and was well grounded in the classic languages. In September 1796 he was removed to Westminster School, where he remained till Easter 1799, not on the foundation. In April 1799 he was removed to Emmanuel College, Cambridge, and remained there till 1806. He graduated B.A. in 1803, and M.A. in 1805.

At the general election of 1800 he was returned M.P. for Abergavenny, borough, in which capacity he continued till 1806, and continued to be one of the representatives of that borough till the dissolution of 1826, after which he was succeeded in his seat by his next brother. He was diligent in his parliamentary attendance, but was not a speaker. In his politics he was a rigid conservative.

Besides being a classical scholar of the highest class, he read carefully all the best works of the Greek and Roman writers with a diligence perhaps unexampled, at least in modern times. He himself states, that while at Oxford, during less than seven years, he read 3253 pages of the Greek poets and historians and philosophers. The last after he had left Oxford in 1829, he read about 40,000 pages; the reading at Oxford amounting to 746 pages annually, while the reading during 1810-20 amounts to 4000 pages annually, which is at any rate more than five times greater.

Mr. Clinton's two great works, the 'Fasti Hellenici' and 'Fasti Romani,' have a European reputation, and are literary works of which every classical scholar of Great Britain may well be proud. The 'Fasti Hellenici' (the 'Civil and Literary Chronology of Greece', 3 vols. 8vo, Oxford, was commenced in 1810, and was published in four separate volumes in 1824, 1827, 1830, and 1834; but the work is now divided into 3 vols., which are sold separately—vol. i. extending from the earliest accounts to the 50th Olympiad, vol. ii. from the 50th to the 124th Olympiad, and vol. iii. from the 124th Olympiad to the death of Augustus. Besides the chronological tables, of which these volumes for the most part consist, they are interspersed with dissertations on the early inhabitants of Greece, the Homeric myths, the value of their poetry, and the influence of Homer, the popular poet, and the formation of the ancient alphabet. The 'Fasti Romani' (the 'Civil and Literary Chronology of Rome and Constantinople, from the Death of Augustus to the Death of Heracles'), 2 vols. 4to, Oxford, was commenced in 1815, and published in 1836. These works have been published in the Gentleman's Magazine. An Epitome of the Civil and Literary Chronology of Greece, from the earliest Accounts to the Death of Augustus, 8vo, Oxford; and in 1853 appeared 'An Epitome of the Civil and Literary Chronology of Rome and Constantinople, from the Death of Augustus to the Death of Hencius,' 8vo, Oxford: two abridgments which are very useful to those students who cannot afford to purchase the larger and more expensive works.

(From the Life of H. F. Clinton, edited by C. J. F. Clinton, 1864; Gentleman's Magazine.)

CLONES. [Mon Ashan.

CLOWES, WILLIAM, printer, was born at Chichester, January 1, 1779; died January 26, 1846. The father of Mr. Clowes was clerk at Oxford, and kept a large press at Chichester; but he died when the subject of this notice was an infant, leaving his widow to support two children with strainedal means. She was enabled, by keeping a small press on a small scale, to remove her children from Chichester to London, where she apprenticed to Mr. Seagrave, a printer at Chichester.

He came to London in 1802, and worked as a compositor with Mr. Teape, of Tower Hill. In 1803 he commenced business on his own account in Villiers-street, Strand, on a capital of 350l. He purchased one press, engaged one assistant; and, after working as a compositor through the day, would often, for two or three consecutive nights, sit up, to press, at the charge of his stock of type free for the next day's demand. It was this energy of character that raised Mr. Clowes to his subsequent position as one of the proprietors of the 'Literary London.' He migrated at the age of twenty-four, a cousin of Mr. Winchester, who had much government business; and by him was recommended for important official work. The name of his wife, Miss Alice, was derived from the name of his patron; and he brought friends around him; and in a few years the humble beginner with one press bad a considerable printing office in Northumberland Street, Strand. This office was burnt down; but a larger rose in its place. In 1826 he commenced steam-printing, the principal founder of Clowes being John M. Gamston, a man of business, and the process being novel, his office had many visitors of literary reputation. Mr. Clowes was always a signal example for the honest and successful manufacturing enterprise to lead the way under new circumstances. He saw that new materials were capable of being adapted to this manufacture, and that the possibility that books might be demanded in sufficiently large numbers to make the new invention of more universal application than was at first considered probable. An action brought by the Duke of Northumberland, whose palace was close to Mr. Clowes's printing-office, to abate the steam-press as a nuisance, was successful—defended; but the printer removed his noise and his dirt, under the award of arbitrators; and the decision was a fortunate one for him. In 1826 he became the compiler of the spacious and well-known publication in Duke-street. Stamford-street. In the course of years the humble establishment of the young Sussex compositor grew into 24 steam-presses and 28 hand-presses, giving employ to 500 hands, and most complete, most perfect, most printing manufactory that had ever been in the world. The creation of literature that should at once reconcile the apparently dissimilar qualities of goodness and cheapness, through demand for books before unprecedented, gave a considerable impetus to London printing. Mr. Clowes's office and premises are described in the Gentleman's Magazine and 'The Penny Cyclopaedia' issued with undervailing regularity for fourteen years from his printing-office. Mr. Clowes was a common man. His powers of arrangement were most acute; he was at once bold and prudent. He was one of those few men who would not recognize the word 'impossible' as one to be lightly employed. He who in 1803 had a few hundred weight of type to be worked from day to day like a bankers gold, would not hesitate, in 1826, to employ the whole of his workforce in laying up and locking up for months in some ponderous blue-book. To print an Official Report of a hundred folio pages in a day or night, or of a thousand pages in a week, was no uncommon occurrence. Mr. Clowes's name will not be associated with the honours of the great classical printers, his was another ambition. He lived in an age when knowledge was to become the inheritance of the many; and he furnished the means of carrying out this literary revolution in a more efficient manner than any of his professional competitors. His name will be frequently associated with the intellectual development of our time. (National Cyclopaedia.)

CLUN, a name given to the lower and harder beds of the Cretaceous Rocks. They are occasionally used for building purposes, and are employed for the foundations of the Churches at Carnarvon, Bangor, and Chester. A large internal work in cathedrals and other large public buildings. This material stands well if not exposed to accidents from mechanical violence. (Anstey, Elementary Geology.)

CLUSIANE. [OITIPINIAE.]

CLUTHALITE. [MINERALOGY, S. 1.]

COAL, an organic combination of mineral substance of a black or brown colour, and in all cases giving indications of having been derived from a vegetable source. Such is a definition that would probably include all those substances which are used in domestic economy and the arts for the purposes of the popularly termed Coal. At the same time it should be stated that the term has at present no special scientific application that is universally admitted, and each investigator thinks himself at liberty to apply the term in accordance with his own view. As the knowledge of chemical principles and methods of investigation has advanced, substances which at one time were regarded as identical have been shown to have a very different chemical composition as well as microscopic structure. This has led to some instances to the discussion of the question, What is Coal?

For instance, in our courts of law, one of the most recent cases—that of Gillespie v. Russell—was tried in Edinburgh in the year 1653. In this case, by an agreement for a lease entered into between the plaintiffs and defendants, the former agreed to grant to the latter a lease of "the whole coal, ironstone, iron-ore, limestone, and fire-clay, but not to comprehend copper or any other mineral whatever." It was alleged by the plaintiffs that, although the defendant had expended upon the premises their iron-ore and ironstone, coal, and fire-clay of workable value, they had neglected these, and had chiefly worked a certain mineral substance which the plaintiffs contended was not to let to the lessee. This was not of the mineral substances specified in the agreement. This mineral was, with much greater value, it was stated, than any which the defendants were permitted to work. Although used as a combustible material, it was alleged that this substance was not coal, and that its chemical, microscopic, and mineralogical characters were not those of coal. On the other hand, it was asserted by the defendants that the mineral in question was coal; that they had been led to seek a lease of the Torbane-Hill estate from the fact that on the adjoining lands of Boghead coal was worked, and sold as coal, being known in the markets by the name of the 'Boghead Gas Coal.' This mineral, they contended, was true coal, belonging to the variety known as Cannel or Parrot Coal. This trial was interesting on account of the large number of chemists, mineralogists, geologists, and microscopists, examined, who appeared in about equal numbers on either side; one set of them contending that the mineral was coal, whilst the others contended it was not. A large amount of interesting facts were elicited concerning the coal and the nature of the deposit, and it is found associated was laid before the jury, who came to the conclusion that, whatever might be the result of scientific investigation in more rigorously defining the nature of coal and limiting the use of that term, both plaintiffs and defendants admit that coal is a term which can be drawn up, and therefore gave a verdict in favour of the defendants.

The same question which has thus been debated in Scotland has also come before the law courts of Germany and of the United States of America with the same diversions of opinion; and we refer to these cases to show the difficulty of defining accurately this well-known substance. It may be regarded in the present state of our knowledge as one of those instances in which the typical form is lost by irregular combination with other and different substances.

That Coal is and must be of vegetable origin seems to be agreed upon by all inquirers, but the question of how to determine that origin in particular cases is the difficulty. Accepting it as a well-known principle that soil after it is subjected undergoes certain chemical changes by which substances with a very different chemical character are produced, such as bitumen, paraffine, &c., these, mixed with the coal itself and the earth, form compounds, which are usually called Coal. It is at about whose nature there may be considerable differences of opinion. This is not improbable the case with the Torbane-Hill mineral, and will account for the peculiarity of both its chemical and microscopical characters.

Coal is generally in a massive form, and is brittle or secrete. It has a hardness of 2 or 2.5, and a specific gravity of 1.2 to 1.75. It is opaque, and has a black or brown colour. Its chemical composition is distinguished by the presence of carbon; in addition, it also yields, on ultimate analysis, hydrogen, oxygen, and nitrogen. On burning it leaves an ash which consists of varying quantities of silica, alumina, and oxide of iron. The carbon and hydrogen are not found chemically united in form to bituminous compounds which are mixed with the coal. It is the presence of these compounds which causes coal to burn with a bright flame; at the same time they give off a bituminous odour. Those institutes of bituminous compounds burn with a pale blue flame, due to carbonic oxides, which is formed in these cases through the decomposition of the water present.

The following table, found on Mr. Musset's Analysis of Coal, is taken from Professor Ansted's 'Elementary Course of Geology, Mineralogy, and Physical Geography':—

</table>
Coal differs considerably in its physical properties, and it has obtained various names in the markets. The minerologists generally divide it into two varieties—

First, Coal without Bitumen.

Second, Coal with Bitumen.

The first variety is known by the general name of Anthracite. It has however various local names, [As-]

Anthracite. It is sometimes very hard, and has a high lustre, and is often iridescent. Besides being used for fuel, it is often made into windlocks, small boxes, and other articles of use. This is especially the case with the Anthracite of Naples. It is the most common form of coal in the Welsh beds.

The Bituminous varieties of Coal present greater differences of structure and appearance, and have a larger number of names. By the above analyses it will be seen that the quantity of Bitumen, or substances resembling it (Browns), differ very much in different specimens of coal. It is generally softer and less lustrous than Anthracite, although occasionally specimens exhibit a very brilliant fracture. Its specific gravity is less than that of Anthracite, seldom exceeding 1.6, whilst the specific gravity of Anthracite ranges from 1.3 to 1.75. The kinds of this coal are known by various names.

The following are analyses of the different kinds of Coal as they occur in the Newcastlem—

Coal is known by its velvet or grayish-black colour. When first thrown on a fire it breaks into small pieces, but on the continued application of heat the pieces again unite into a solid mass or cake. It burns readily with a yellow flame, but on account of its caking quality it is likely to clog the fire; unless it is frequently stirred. The Newcastle beds mostly yield this form of coal.

Cherry Coal resembles in external appearance the pitch coal, and when exposed to heat it cracks and flies, but does not cake. It is very brittle, and on this account much loss is occasioned in mining it. It burns with a clear yellow flame. This kind of coal occurs in the Glasgow beds.

Split Coal is a variety found in connection with the last, and is remarkable for its hardness; for which reason it is sometimes called Hard Coal. It is found at Glasgow.

Carneal Coal has little lustre, is very compact and smooth in its texture, and breaks with a large conchoidal fracture. It is also known as a kind of pitch coal, but does not crack on heating out melting. In consequence it has been employed in the making of candles—hence its name. It is often employed for making inksands, small-boxes, and other articles of use.

At the Great Exhibition of 1851 several models of public buildings, monuments, &c., were exhibited, formed of Carbon Coal.

The above coals are those most commonly burned. Their goodness for heating is tested by the quantity of water they evaporate. The following are the results of some recent experiments—

1b. oz.

Common Scotch Bituminous Coal | 5 14

Carr's West Hartley Main (Newcastle) | 7 5

Moffat Bituminous Coal | 0

Pure Welsh Anthracite | 10 8

From which it will be seen that the heating power of anthra-

cite nearly doubles that of some bituminous coals.

"Brown Coal" of Anthracite is sometimes given to less perfect varieties than the last. Specimens of these coals have a brownish-black colour, and burn with an emphyse-

matic odour.

On playing sections of Lignite under the microscope, the structure of the wood of the plant forming it can be readily detected. This is not the case with the other kinds of coal, where, although the woody fibre can be frequently made out, it has evidently undergone considerable change. Professor Quekett has well described, projects the term to those mineral sub-ances alone which are evidently made up of the woody tissue of plants. He maintained that the Torbanite mineral was not coal, on the ground that it was not composed of the debris or remains of vegetable woody tissues. Although woody and also seen in the Torbanite mineral, Professor Quekett maintains that this has been accidentally introduced, and that no true vascular or spiral tissue is found in coal.

"Brown Coal" is frequently applied to coal more recently deposited than that of the great coal-beds of the world, and this quite independent of its structure or any peculiarity in combustion. Lignite is also a term applied to the semi-carbonised forms of wood which are frequently found deposited later than those of the coal deposits. Most of these varieties of coal contain a large quantity of water, and the quantity of matter given off at a moderate heat by distillation is at least equal to that of the carbon contained.

"Dysoxid is a yellow or grayish highly laminated sub-

stance, often found with lignite, and burning vividly, and spreading an odour of asahadetta." (Aned.)

Jet is another variety of coal belonging to the bituminous series, and occurs in elongated reiform masses, and sometimes in the form of branches with woody structure. It is soft and brittle, with a conchoidal fracture. Its specific gravity is but little greater than that of water. It is opaque, of a violet-colour, and has a brilliant and resinous lustre. It is found in Saxony, and also in the Prussian amber-mines in detrital fragments. It is sometimes washed up on the shores of Great Britain. The finer sorts are used in the manufacture of ornaments and snuff-boxes of various kinds. The coarser sorts are burned as fuel. Jet is used when burning a greenish flame and a strong bituminous smell, and leaves a yellowish ash. It contains about 57 per cent. of volatile matter.

For an account of the origin of Coal, and the beds of Coal on the surface of the earth, see Coal Formation and Coal Plants.

COCIDAE. [GALLINULAE.]

COCKBURN, ADMIRAL, THE RIGHT HONORABLE SIR GEORGE, G.C.B., who represented a branch of the same family as Lord Cockburn, was born in 1759, entered the navy in 1781. Having served in the East India, Home, and Mediterranean stations, in 1795 he co-operated with the Austrian troops in Piedmont, and took part in the capture and blockade of Leghorn. He subsequently received an appointment to command a fleet against Martinique, which resulted in that island being ceded as a British colony. In 1812 he was sent as commissioner
COC 148 COL

for reconciling Spain and her transatlantic colonies. He was com-pions in the hostilities with America in 1813 and 1814. He was a collateral of Sir Fullerton and retired from public life by a sister of the wife of the first Viscount Melville, and represented an ancient Scotch family which has produced many distinguished members. He was born in 1770, and called to the bar in 1806 in the same family prominent in Scotch law, belonging to the Tory school, but although the Scotch patronage of the crown for many years was dispensed by Lord Melville, Mr. Cockburn in early life adopted liberal opinions. It was not until November 1830 that any high legal position fell to Mr. Cockburn, when he became solicitor-general for Scotland, upon the promotion of Jeffrey to the attorney-generalship. He had however long before this time been to considerable eminence in his profession, and was particularly distinguished for the ability of his advocacy, and he took an active part in the prosecution of the Cato affair. Among other cases in which he was engaged may be particularly mentioned that of the Queen'sberry trial, in which considerable property was at stake. He had also brought before the House of Lords, the act "annulling the charge drawn up by Mr. Cockburn against the observation of the bench, and even as a young man his papers on feudal law had met with general approval.

Such a man as Cockburn could not long remain without reaping a more permanent reward than the solicitor generalship. Accordingly in 1834 he was promoted to the Scottish bench as one of the lords of session, to which three years later was added the further appointment of a lord commis- sant of the admiralty, in which he remained till he was surpassed by few in his clear enunciation of law, and in his charges to juries. He was distinguished by a skilful detection of whatever was false in principle or in evidence, as well as by the breadth and grasp of his legal judgments, which soon appealed to the public.

Besides the life of his friend Lord Jeffrey in 2 vols. (1852), Lord Cockburn published only one small pamphlet, which was entitled "On the best way of spoilling the beauties of Edinburgh," which was an early contributor however to the pages of the Edinburgh Review; and it is said that an article from his pen in that review was mainly instrumental in causing a reform in the method by which Scotch juries had been previously chosen.

As a friend, neighbour, and citizen, no less than as a relative, Lord Cockburn was beloved. His death, which happened April 26, 1854, while he was on circuit at Ayr, was preceded by an illness of but a few days' duration. He left a large family by his widow, who is sister of the wives of the late Scotch judges, Lords Fullerton and Dundas, etc.

COD-FISH. [Monnkhur.]

CODEIA. [Chemistry, &c.]

CODRINGTON, SIR EDWARD, ADMIRAL, G.C.B., was born 1784. In 1806, when he was appointed to the command of the Orion, 47, and was engaged in the battle of Trafalgar. For his ser-vices in this victory he was rewarded by a gold medal. He left the Orient on 25 December, 1806, and in November, 1808, he was appointed to the Palisado, and on the latter ship he sailed under Lord Gardner in the expedition to Walcheren, and was thanked for his services in forcing the Schelde, in August 1809. In 1810, 1811, and 1812, Captain Codrington was on the Channel fleet, attended the defence of Cadiz and Tarragona, and in co-operating with the Spanish patriots in Catalonia. In January 1813 he returned to England.

In 1814 Captain Codrington sailed to North America, and while there was promoted to the rank of rear-admiral, and was appointed captain of the fleet under Sir Alexander Cockrane. He took part in the attack on New Orleans. At the conclusion of the war with the United States he returned to England, and in 1815 he was created a knight commander of the Bath, January 2, 1815. He attained the rank of vice-admiral July 10, 1821.

Sir Edward Codrington was appointed, November 1, 1826, commander-in-chief of a squadron in the Mediterranean destined to observe the Turkish fleet, and hoisted his flag on board the Asia, 84. He was joined by a French and a Russian squadron, and the battle of Navarino took place October 29, 1827; when the Turco-Egyptian fleet, consisting of 21 ships of war, was almost entirely destroyed. For his services in the battle Codrington was distinguished by the dignity of knight grand cross of the Bath; but as there was much doubt among politicians as to the propriety of destroy-ing this fleet, and the Duke of Wellington admitted that it was a "mistake," Sir Edward proceeded on parole from the Mediterranean in April 1828. In 1828 he was elected M.P. for the borough of Devonport, and was re-elected in 1835, and again in 1837. He was of liberal politics, and very popular. In 1837 he was attainted the full rank of admiral, and on the 22d of November, 1839, was appointed commander-in-chief at Portsmouth, when he resigned his seat as a member of parliament. He occupied his station at PORT-mouth for the usual term of three years. He had a good service pension of 300 l. a year. He died in London, April 21, 1851.

CÔLÈBÔGYNE, a genus of plants belonging to the natural order Euphorbiaceae. This genus was named by Mr. J. Smith from a specimen grown in the Royal Gardens at Kew. It is remarkable for the fact that being dioecious, the pistillate flowers of the male plants have ripened their fruits, which contain seed containing a perfect embryo without the presence of the staminate plants. This appears to be quite an ex-ceptional case to the law of production of the embryo by the agency of the pollen-grains of the staminate plants. Further observation may detect some hitherto undiscovered means by which the pollen-cells of perhaps an allied plant may come in contact with the pistil of the Colèbôgyne.

CÔGGESHALL, [Essex.]

COLBY, THOMAS, Major-General in the army, and one of the Directors of the Ordnance Survey, was born at Rochester, 1st of September 1784. When his father, Captain Colby, of the Royal Marines, sailed with the fleet under Lord Howe, he was sent to Dr. Crockell's school at Northfleet, and from thence he entered the Royal Military Academy at Woolwich. He obtained his first commission as second lieu-tenant of engineers in 1801, being then but seventeen years of age. His diligence and success in scientific study were such that in January of the following year, at the special request of Captain Mudge, then superintendent of the ord-nance survey, he was appointed one of the assistants in that great work. Entering at once on his duties, he justified the expectations that were entertained of him by his industry and con-scienctious activity which he brought to the work of surveying. He was on a tour of inspection in Cornwall, in 1803, when he lost his left hand by the bursting of an old pistol, and continued his labors upon the grand survey of England from a fragment of the barbel, that he felt the effects of the acci-dent for the rest of his life whenever he attempted any long-continued mental exertion. Though the loss of his hand was a hindrance to the active discharge of his duties, Colonel Colby carried on the execution of his duties to the best of his merits, that he kept the young lieutenant permanently attached to the survey.

In 1803 Lieutenant Colby was serving at Dunnone, one of the prominent points of the survey: in 1804 at Beaumaris; and in 1806 with the seventh sector at Burleigh Moor and Delamere Forest. The winter months he passed in the
He was one of the party that accompanied Biot on his trip to Shetland in 1817, when, in compliance with the King's command, he was permitted to observe on the line of the English arc. A coolness however arose between Biot and Colby, and while the latter, undeterred by fog or storm, made his observations with the sector on the rock of Balta, the former carried on his measurements on the island of Agaist; and Colby afterwards assisted in connecting the French with the English triangulation by the observations across the straits of Dover.

In 1820 Captain Colby was elected a Fellow of the Royal Society; he took an active part in establishing the Astronomical Society; and General Mudge having died, he was appointed his successor as superintendent of the Survey, and in the Board of Longitude. In 1821 he was promoted to the rank of major, and was placed on the staff of the island of Ireland. In this work the usual mode of proceeding was modified: the survey was made dependent on actual measurements with the chain, with a trigonometrical point fixed for every 400 acres; and the whole series of operations was so unitedly combined that one person became a check on the other, and the utmost accuracy was arrived at, although the number of persons employed exceeded two thousand, mostly from the native peasantry. A change was also made in the method of anchoring: the survey vessels, rather than anchors to the mile, all the principal farms, fields, and inclosures being represented, so that the maps have ever since been regarded by the government, land-proprietors, and surveyors, as authentic plans of all the estates in the country.

Frequent and laborious as the surveying works, and the Irish census, have all been based upon them. They are comprised in 1839 sheets.

In 1832 Major Colby became lieutenant-colonel, and in that year he obtained the Duke of Wellington's sanction for raising and training the most efficient and able body of men to aid in the Irish survey, as the want of really efficient assistants was felt at first as a serious hindrance to the progress of the work. In the course of the operations Colby was elected a Fellow of the Royal Society, and became a member of Lough Foyle, with 'compensation-bars' which he had himself invented. He had carried on a series of experiments on the heating and cooling of metal rods, and he succeeded in constructing a bar of brass and iron in combination, the extremities of which remained always the same distance apart whatever might be the temperature. Such is the exactitude obtained with this apparatus that it has since been used in measuring a base of eight miles at the Cape of Good Hope, in the re-measurement of the English bases in those parts of the world where no other calculations have been afforded, and in the triangulation of the great arc of India.

In 1838 Colonel Colby resumed the triangulation of Scotland, which had been suspended; and from this date up to his promotion to the grade of major-general in 1846, who he was in consequence of the service his connection with the survey ceased, he continued his usual active and energetic superintendence of the various operations. He brought the engraving of the English maps to an excellence never before achieved. The seconds of latitude and longitude were marked on the margins, and he co-operated with Sir George De la Beche in introducing the geographical facts and features which have since become so important a part of the survey. He took the necessary measures for a series of tidal observations round the coast of Ireland, for the purpose of establishing a true datum level: "the most important series of tide-observations," says the astronomer-royal, "that has ever been made."

Through all his scientific career Colby never parted from a use of his own, and his patients would in some degree be served in the hospital of industry and science, which he had so carefully established. Once, when encamped on Sliove Donard in Ireland, the summit of Sea Fell in Cumberland became visible at the distance of 111 miles, and after many trials the instrument was brought to bear upon it. "Colby was on the point of successfully finishing his observation, which would have been a grand triumph, including the longest side of a triangle ever attempted, when an officer on entering the observatory accidentally struck his elbow, and threw the telescope off the object. A momentary effusion of his tears, but though he could not again succeed, and the object was therefore lost, he never afterwards alluded to the subject."

"Drawing Room" at the Tower, computing and preparing the results for publication, and superintending the construction and sogering of the ordnance scale of 1 inch to the mile. So thoroughly was he identified with that great national work, that the history of one becomes in great measure the history of the other. In 1807 Colby was promoted to the rank of captain. The third volume of 'An Accomplishment Manual' was published in 1811, and his name appearing jointly with that of Colonel Mudge on the title-page, showed how highly his services had been appreciated by his chief. In 1815 it was determined to extend the meridian line into Scotland, a task which was specially assigned to him, in the course of which Colby was remarkable. Within the next three years he visited and observed at the principal stations beyond the Tweed, besides attending to his official business at Edinburgh. The proving labour and activity required for a season of observation on the hills would appear incredible to one unacquainted with the nature of the work. Besides the mental exercise of keeping all the subordinates to their duty, so as to produce harmony in the results, there was much personal fatigue to be endured in long walks over the country, together with storms and wearisome delays on the mountain tops. But with Captain Colby duty was paramount, and he cared not for privation, so that the work was performed in his accustomed manner. Colby's "drawings of the hills" gives a striking picture of the toils and hardships experienced: "It was no uncommon occurrence," he remarks, "for the camp to be enveloped in clouds for several weeks together, without affording even a glimpse of the sun or stars. And then, at the moment the clouds would break away or subside into the valleys, leaving the tips of the mountains clear and bright above an ocean of mist, and the atmosphere calm and steady, so as to admit of the observations for which the party had waited days and weeks to be taken in a few hours. At times the tents would be blown down by storms—or the camps would be whitened by a fall of hail or snow in July—or the camp taking two or three of the junior officers and a few men would start on a survey, necessitating a course by direct compass for the peaks that seemed most suitable, regardless of the nature of the intervening country. In these explorations they walked from thirty to forty miles a day, wading streams, crossing bogs, scaling cliffs, and sliding down into rocky valleys, Captain Colby ever the foremost; and when they came to a summit which his experience told him was suitable for a station, he would help with his own hand in handling up the great pile of stones by which it was to be marked, selecting the point points sometimes the resting-place at night would be a level bar where no other food was to be obtained than the national porridge; at others the weary explorers rested under a ducal roof—and on the west coast during the hot months they were tormented by the bites of the considerable mice. In one trip in 1819 the party walked 566 miles in twenty-two days. From this brief summary, a notion may be formed of the severe labour of the survey, apart from the scientific duty of observing with the instruments, which on all favourable occasions was continued from sunrise to sunset.

Captain Colby's activity and kindliness of disposition were not less apparent in camp than on the station-hunts. He would assist in erecting houses to "shelter the soldiers; and occasionally join with the men in a game of quoits, or in putting the stone or crowbar, and was a warm promoter of their feast at the close of each trigonometrical season." He was quite indifferent as to personal fame, but not so to make the name of his officers, and he at times permitted them to publish portions of the work in their own names rather as principals than assistants. His command over his temper was perfect; but he disliked to be disturbed by curious visitors when busy with observations for which he had long waited the opportunity. Once, while encamped at Sliove Donard in Ireland, the summit of Sea Fell in Cumberland became visible at the distance of 111 miles, and after many trials the instrument was brought to bear upon it. "Colby was on the point of successfully finishing his observation, which would have been a grand triumph, including the longest side of a triangle ever attempted, when an officer on entering the observatory accidentally struck his elbow, and threw the telescope off the object. A momentary effusion of his tears, but though he could not again succeed, and the object was therefore lost, he never afterwards alluded to the subject."
and parliamentary borough, and the seat of a Poor-Law Union, is distant 145 miles from Dublin. The population in 1851 was 3692, exclusive of 342 inmates of the Union workhouse. The Coleraine Canal, a day-deal, one member to the Imperial Parliament. The paling, lighting, &c., of the town are under the care of 21 town commissioners. Coleraine Poor-Law Union comprises 20 electoral divisions, with an area of 112,560 acres and a population of 12,161.

Coleraine is situated on both banks of the river Bann, at a distance of 4 miles from the sea. The principal part of the town is on the right bank, and consists of a central square called the Diamond, with several leading streets diverging from it. The town is supplied with good water from the Bann and a great arch of the Bann Bridge of 1799; and a sluice on the left bank of the river is a stone structure of three arches, 388 feet long and 32 feet in breadth, erected at a cost of 14,000L.

There is a great thoroughfare by this road between the northern parts of the counties of Antrim and Londonderry. The principal churches of Kilcowen and Coleraine stand in the respective divisions on either side of the river. There are also two Roman Catholic chapels and six meeting-houses of various denominations of Dissenters, an Endowed school, a National Model school, and a savings bank. The old court-house and town-hall stands in the centre of the Diamond. There is a new market-place with a commodious market-house. The town is lighted with gas. Vessels of 200 tons burden can anchor at the quay, but those of a larger tonnage have to work in the port. A trade of Coleraine is conducted from the harbour of Port Rush, 5 miles distant on the coast near the embouchure of the river. At Port Rush is a harbour formed by two piers of 600 feet and 650 feet in length, enclosing an area of 6 acres, in which the vessels of Coleraine lies at anchor.

The customs duties of the Coleraine district in 1856 amounted to 500L.; the excise duties amounted to 40,644L. The number and tonnage of vessels belonging to the port in 1856 were ten vessels of 293 tons aggregate burden. The entrances and clearances at the port in the coasting and cross-channel trade in 1856 were —Sailing vessels, inwards 120, tonnage 6080; outwards 44, tonnage 1350: steam vessels, inwards 21, tonnage 29,269; outwards 51, tonnage 11,353. In the coasting trade the vessels of 100 tons or upwards entered 1922 tons, and cleared 4 vessels of 1790 tons. The principal trade is the manufacture and bleaching of linens and the salmon-fishery. A fine description of linen manufactured here is known as 'Coleraine.' The fisheries (of salmon and eel) are the property of the Irish Society, who farm them out at an annual rent of 1200L. Upwards of 300 persons are employed as water-bailiffs in the protection of the salmon fishery from July 1st to November 30th.

The market days are Wednesday and Saturday, and the market is held on Monday, Wednesday, Friday, and Saturday. There are tanneries, bleach-grounds, paper-mills, and soap and candle works. Quarter sessions of the peace for the county of Londonderry are held in Coleraine. Thefrequency of death in Coleraine is very high. The female population of Coleraine in the Presbyterian Church arrangement is the seat of a Presbytery of the General Assembly, consisting of 16 congregations.

Coleraine is remarkable in early Irish history as the place in which Patrick founded a Christian bishop already located on his first progress through the northern parts of Ireland. A castle was built here in 1213 by Thomas Mac Uachtar, a Scottish adventurer. One of De Courcy's followers, called De Sendall, also erected a castle very soon after the conquest. The present town stands on the site selected by the Irish Society in 1613. It was at first fortified by an earthen wall with bastions. The place held out against the rebels in 1641. In 1653 the whole customs of the port amounted to only 152, 56. 4d. The neighboring districts are rich and well cultivated. A fall of the Bann over a ledge of rock of 12 feet high, at the Cutts, about a mile above the town, adds considerably to the picturesque interest of the environs.

COlERIDGE, Samuel Taylor, the eldest son of Samuel Taylor Coleridge, was born at Cledenon, near Bristol, Sept. 21st 1796. Two sonnets of his father are commemorative of his birth; and an exquisite poem of Wordsworth, 'To H. C. six years old,' describes the peculiarity of the child, 'a boy of wondrous face and of deep soul, associated with two poems of his father, 'Frost at Midnight,' and 'The Nightingale.' In 1800 S. T. Coleridge went to reside in the Cumberland Lake district; and there Hartley was reared; having a brother, Derwent, four years younger than himself, and a sister, Sara, six years younger. He was taken to London in 1807; and the various sights which he saw made an indelible impression on his mind, the effect being immediately apparent in the composition of those extraordinary and visionary works, which, in the year 1816, he printed with the title of "Slopes of Insolence." In 1826 he was placed, as also his brother Derwent, as day-scholars of the Rev. John Dawes, at Ambleside. As a school-boy he writes as a story-teller were unique; his imagination was absolute and romantic, whose recital lasted to the very last moment of his life. It has been said that what he wrote in one day—by the living voice of Coleridge, Southey, and Wordsworth, Lloyd, Wilson, and De Quincy.' In 1814 Hartley left school; and in 1816 went to Oxford, as a scholar of Merton College. His extraordinary powers as a converser, and his numerous invitations to wine-parties, were beyond a doubt—two—by the living voice of Coleridge, Southey, and Wordsworth, Lloyd, Wilson, and De Quincy. In 1814 Hartley left school; and in 1816 went to Oxford, as a scholar of Merton College. His extraordinary powers as a converser, and his numerous invitations to wine-parties, were signals to him in two ways—he used great freedom of remark upon 'all establishments,' and he acquired habits over which he had little subsequent power of control. He passed his examination for his degree in 1815, and soon afterwards obtained a fellowship at Oriel, with high distinction. An unhappy issue followed this honourable and independent position. "At the close of his probationary year, he was judged to have forfeited his Oriel fellowship, on the ground, mainly, of extravagance. His emoluments were 200L. a year; but we have no record that any friend stepped in to rescue one, so otherwise blameless, so sensitive, so unfit for any worldly struggle, from the permanent consequences of this early error. His brother, who records this painful epoch of his life, with his mortification, says, "He died, his family, his friends, his admirers, and his home, in poverty—" and the ruin of his fortunes served but to increase the weakness which had caused their overthrow." It is unnecessary for us to follow the biographer's explanation of some of the causes which led to this unhappy result—his morbid consciousness of his own singularity—his despondency at being unsuccessful in obtaining University prizes—his incapacity for the government of the pupils whom he received while at college—his impiance of control, and a belief that he was watched by those who knew his infirmity and mask their revulsion of manifestations of peculiar temperament. His qualification for future active exertion was irretrievably destroyed.

After leaving Oxford, Hartley Coleridge remained in London two years, occasionally writing in the 'London Magazine,' in which few of his minutes were published. In 1817 it is reported that he will be established at Ambleside to receive pupils. The scheme failed; and after a vain struggle of four or five years, the attempt to do what he was unqualified for was abandoned. From 1819 to 1823 he was a licentiate of the College, of the Lake district—idles, according to ordinary notions, but a diligent reader, a deep thinker, and a writer of exquisite verses, and of prose of even a rarer order of merit. From 1823 to 1831, he contributed to 'Blackwood's Magazine.' In 1834 he married Mrs. Wilson of Oxford, and he is now publisher at Leeds; for whom he produced a volume of 'Poems,' and those admirable biographies of the ' Worthies of Yorkshire and Lancashire,' which make us more than ever regret that one who wrote with such ease and vivacity, should have accomplished so little. In 1834 his father died, having, in a cordial to his will, expressed great solicitude to ensure for his son that "tranquillity indispensable to any continued and successful exertion of his literary talents," by providing for him, through the proper application of a bequest after the death of his mother, "the continued means of a home." Mrs. Coleridge died in 1845, and an annuity was then purchased on Hartley's life. Meanwhile, he lived with a humble family, first at Grasmere, and then at Rydal, a house which he had watched over by a kind spirit with whom the was an intimate, and beloved by all the inhabitants of the district. His illustrious friend Wordsworth was his close neighbour; and the house of the poet was always open to the child-like man of whose wayward career he had been almost preceding. In 1839 Hartley wrote a life of Massinger, prefixed to an edition of his works published by Mr. Moxon; and during the latter years of his life he wrote many short poems, which appear in the two volumes published by his brother, 'With Love, in Memory of Wordsworth.' He was a frequent visitor in the cottage which he had long occupied on the bank of Rydal Water, on the 6th of January 1849; and was buried in Grasmere churchyard. His grave is by the side of that of Wordsworth.
Coleridge was born at Keswick in 1801. Until her marriage she resided in the house of Robert Southey, who married her mother, and who had, as a profound influence over his intellect, the formation of her mental character must be largely ascribed, though she possessed in a remarkable measure the intellectual characteristics of her father. Her opening womanhood was spent at Keswick in the diligent culture and exercise of her native taste. She learned the Latin of Martin Dobrisheffer, a translation suggested by Southey, and the admirable execution of which he has commemorated in a stanza of his 'Tale of Paraguay.' In 1829 she married her cousin, Henry Nelson Coleridge. (Crollojans, ii. 64.

She now gave herself to her domestic duties, and her next literary production was prepared as a Latin lesson-book for children, 'Pretty Lessons for Good Children,' and speedily passed through several editions. On the death of her father in 1834, her husband, who was the poet's literary executor, set himself to the task of preparing such of the poet's uncompleted works as would serve best to exhibit him as a theologian, philosopher, poet, and critic, and Sara Coleridge helped him with her pen to this work. During her husband's life much of the collation and a considerable portion of the annotation fell to her share. After his death she did not hesitate to take upon herself the whole of the arduous labour. The 'Aids to Reflection,' 'Notes on Shakespeare,' 'Dramatists,' 'Addresses to the Academy,' and 'Times' were edited by her alone, and to some of them were prefixed elaborate discourses on the most weighty matters in theology, morals, and philosophy, which were discussed in a clear and vigorous style, with a closeness of reasoning and an amount of erudition quite remarkable in one of her sex. Sara Coleridge, like her father, had in no stinted measure the imaginative as well as the reasoning faculty. Her fairy tale, 'Phantasmion' wanted only the colouring of verse to have been equal to the best of the nursery tales, and more besides. It is a series of poems of the age; but in prose its often exquisite imagery and delicate shades of thought and feeling seemed to lack some clear and palpable intention; and it was regarded for the most part as vague, visionary, and obscure. Probably it will be on her commentaries upon her father's works—from which they are not likely to be by any future editor dissociated—that her fame will ultimately rest; but her rare acquirements and rarer gifts being thus expended on annotations, are now scarcely likely ever to meet with their due reward, and her name and memory have suffered accordingly. She died May 3rd, 1852. At her death she was engaged in preparing a new edition of her father's poems, which was completed and published by her brother, 'Poems of T. C. Coleridge and S. Coleridge,' 1832.

Coleshill [W. Wickershams.]

Collins, William, R.A., was born in Great Titchfield-street, London, September 18, 1757. His father, a native of Wicklow, was the author of various works which attracted some notice in their day; among others a poem on the slave trade, a novel entitled 'Memoirs of a Picture,' and a 'Life of George Morland.' The elder Collins was a picture-dealer as well as an author, though in no calling had he had much pecuniary success. Morland was a friend of his, and when his son began to exhibit a fondness for art and some skill in drawing, he readily obtained Morland's consent that the youth might stand beside him and watch him paint. William made tolerable progress in his pictorial studies. He entered in 1767 as a student at the Royal Academy at the same time as Etty, and in after life the two R.A.'s were fond of comparing their early drawings and subsequent progress. His earliest appearance as an exhibitor on the walls of the Royal Academy was in 1797, when he contributed two small 'Views on the Banks of the Thames,' and from that time with the exception of two years when he was away in Italy, he did not miss an exhibition for the remaining nine-and-thirty years of his life. His father's death in 1812 threw upon the young painter sacred duties, and these seem to have stimulated him to increased exertions. For some time he was employed to paint portraits as the readiest means of securing a moderate income, but his landscapes and rustic groups began to make their way, and he was soon enabled to follow the bent of his genius. Almost from the first he showed his fondness for painting groups of homely children engaged in some favourite diversion, or taking part in some juvenile trick; but it was not till the year following his election as associate of the Academy that his landscape work began to be noticed. As the path—the representation of coast scenery—which perhaps most surely led him to fame andfortune. From that time—indeed, for some three or four years previous—Collins never wanted patrons; his course from first to last was one of unbroken success.

As a painter of rustic life, or rather, perhaps, we ought to say of country children and homely country scenery, Collins had hardly a rival. He watched the habits and noted every movement of these groups of children. He could not be seen to fall on the bird's tail; exhibiting the fresh-found nest; buying the cherries—however the youngsters were represented the truth of the portraiture was at once apparent; and some quaint or novel incident was sure to be added, which marked more graphically than even the principal feature, the keenness of the painter's eye, and the skilfulness of his hand. In his coast scenes these characteristics were equally visible; and equally evident also was his happiness in the choice of his subject, in the attempt to surprise or excite. The painter knew exactly what was within the range of his powers. He saw his subject clearly; knew what he meant to accomplish, and seldom failed to accomplish it. Hence his pictures, apart altogether from those abounding in children, and therefore more or less arising from an excess of anxiety to render his work perfect. But, with increased command over his materials, he gradually acquired greater breadth and vigour; and though he always continued to finish his pictures with scrupulous care, he early recognised the truth of the axiom that more correctness of detail is not sufficient. And then with his technical and manipulative skill there was shown a close study of nature. The receding or advancing wave, the moist or parched sand, the teeming clouds, every phase and every feature of earth, water, and sky, and the varying effects of light and shade, are all represented. No wonder that in a country like this, where every one who can turn to the scenery of nature with never-tiring zest, such faithful transcripts of her commoner aspects, unadorned by the more ornamental picturesque, who, to city dwellers at least, always seem so genuine a part of the scenery, should have found abundant admirers and ready purchasers. In 1830 Mr. Collins visited Italy, and remained there nearly two years; diligently availing himself of every opportunity of examining the works of the great masters, but at the same time filling his sketch-book with transcripts of the more striking features of the natural scenery and careful studies of the monks and peasants, and, above all, of the children, in that land of lazy enjoyment and perennial beauty. On his return in 1839, he sent to the academy at the fruits of his journey two views in Naples: one with a group of young lazaroni playing the game of 'arroguglia;' the other with 'Poor Travellers' at the door of a Capuchin Convent;—also a view at Subiaco. They manifested an increase of artistic knowledge and power, and were greatly admired. The next year he appeared in quite a new branch of art, that of historical painting. With increasing years Mr. Collins had been increasingly in the depth and earnestness of his devotional feelings, and he not unnaturally felt a strong desire to represent in his own way the scenes on which his imagination loved to dwell. 'Our Saviour with the Doctors,' and 'Christ appearing on the Academy Bridge,' which was exhibited in 1840; 'The Two Disciples at Emmaus,' of 1841. They of course attracted attention, and supplied a topic of conversation in art circles, nor did they fall of purchasers; but it was felt to be a positive relief by the great body of the painter's admirers when, after a little coying with a certain scenery in one or two small pictures exhibited in 1842, he

Collins was elected R.A. in 1890; in 1840 he was appointed librarian to the Academy, but resigned it on finding that its duties commanded but little of his attention. As the meetings of Collins are to be met with in most of the great private collections in this country. In the National Gallery the foreigner would look in vain for a specimen of this, one of the most thoroughly national of English painters. Fortunately, the Victoria and Albert Museum contains a certain time to-day: there may be seen an excellent example of his delineations of rustic enjoyment in 'Happy as a King,' painted in 1826; one of his pleasant coast-scenes, in 'The Shrimpers—Ever-Lasting,' purchased in 1822; and his 'Fisherman's Wedding,' painted in 1855. Mr. Collins married in 1852 the daughter of Mr. Geddes, A.R.A., and sister of Mr. Carpenter, the well-known portrait-painter; and by her had two sons.

COLINE. [Lycasana.]

COLUMBIA, a genus of Plants belonging to the natural order Rhamnaeceae. It has a spreading 5-cleft calyx; petals 5, obovate-convolute; stigmas 3. Fruit capsule, dehiscent, trilocular, girded at the base by the calyx. The seeds are furnished with a short stalk. The species are shrubs with alternate, quite entire, or crenulated leaves, netted with distinct hair-nerves, smooth but usually pubescent or rusty villous. The flowers are in axillary short crowded cymes, or in racemes or panicles.

C. formentum. Fermented Snake-wood, is a native of Guinea; the bitter bark of which tree is said to bring on violent fermentation in the liquors into which it is thrown. There are several other species described, natives of South America. There is a certain stoppage in the use of this plant, as none of them are of any known use, and are not worth cultivation except in general collections.

COLUMBITE. [Columbium.]

COLUMYON. [Devesirke.]

COLZA, [Brassica.]

COMBE, DR. ANDREW, was born in Edinburgh, October 27, 1797, the fifteenth child and seventh son of a family, which numbered seventeen in all. His father was a respected gentleman, and a man of superior mind and integrity; his mother also was a superior person. Educated in his boyhood and youth very much under the care of his elder brother George, the well-known phrenologist, he chose the medical profession; and, having studied at Edinburgh and Paris, and taken the degree of M.D., he began practice in Edinburgh in 1823. A pulmonary complaint under which he had laboured since 1819, and which obliged him to make frequent journeys into warmer climates, precipitated him from such an active career as a physician. In 1835 he was appointed Consulting Physician to the King of the Belgians. As early as 1818 he had, like his brother George, given his attention to phrenology and became a convert to it; and both of them while professors of this new science, continued to advocate its doctrines through the 'Physiological Journal.' He was also a distinguished writer on general scientific and medical subjects. The following is a list of his most important separate works:—Observations on Man.

COMTE, AUGUSTE, a French philosopher, whose peculiar system of views has been put forth by himself, and is generally known under the name of 'The Philosophy,' was born within a year or two of the close of the last century. His family was strongly Catholic and royalist. Educated at one of the French lycées, he gave very early proofs not only of a speculative turn of mind, but, as the son of a naval officer, of a love for sea voyages. He was educated in the College of St. Sulpice, and in 1828, having left school, entered the ship 'Bourbon,' Captain Dupuis, He had already extended his views to social questions, and became possessed with the doctrine that the time had come when all science and all philosophy must be treated from the social, as the supreme point of view. It was with a views and aim of this kind fermenting in his mind, that while yet a mere youth, he was involved within the powerful vortex of the Saint-Simonsian school, which, immediately after the restoration of 1815, began to figure in Paris. The genius of Saint-Simon, then between his fortieth and sixty year, drew around him, as by a kind of magnetic attraction, a number of ardent young men, whom he indoctrinated with his views, and almost all of whom—notwithstanding that few of them in mature years have adhered to the system—have occupied a conspicuous place in the history of modern thought. One of these was the youngest—the Benjamin, as he was called, of the Saint-Simonsian school. Saint-Simon had high hopes of him; and when, about 1825, the school took a more scientific turn, and espoused the exposition of the scientific basis of their system, it was on Comte that the preparation of the work devolved. The work entitled 'Système de Politique Positive' however only partially satisfied Saint-Simon, who said that while it "clearly understood the generalities of his system from the Aristotelian point of view," it overlooked "their religious and sentimental aspect." The truth is, Saint-Simon and Comte were beginning to part company. The discrepancy did not sharpen the distinction between the two. Comte always respected the work of Saint-Simon, including Saint-Simon— including Enfantin, Bazard, Rodrigues, and Augustin Thierry—who remained faithful to the views of their master, and set about forming an organisation for their farther propaganda. Comte succeeded in this organisation, Saint-Simon, and represented his temporary connection with that enthusiast as rather an interruption to his own true intellectual development than a furtherance of it; but in his main line, the system of views and the subsequent works and the cardinal speculations promulgated by Saint-Simon when alive, that, unless we can suppose that the pupil promoted the master to a greater extent than usually happens in such cases, it is impossible to acquit Comte of these high-flown ideas, which have been the subject of allusions to this part of his education. In 1826 M. Comte was seized with what he calls 'a cerebral crisis,' which for the time was believed to be irrecoverable insanity. He did recover however, and lived to promote the philosophy with
which his name is associated. Snapping himself by teaching mathematics—in which capacity he was professor at the Ecole Polytechnique, till differences with his colleagues and the accession of Louis Napoleon to the empire deprived him of his office, and reduced him to a state of indigence in which his chief support consisted of voluntary contributions from friends who in France and England he published during the last seven and twenty years a series of works, all devoted to the elucidation of his 'Positive Philosophy,' and in which even those who have no sympathy with that system in its abridged and popular form, can admire or even abhor it. He recognised great power of intellect, and an extraordinary fertility of generalisation on all subjects.

First, published at intervals in six large volumes, between 1830 and 1848, came out his greatest work, entitled 'Cours de Philosophie positive.' In this work he propounded and developed his main doctrine, which is, that the human mind has, by a natural law, passed through three successive stages in its thoughts upon all subjects; namely, the theological stage, in which phenomena are accounted for by the supposition of the agency of supernatural beings to produce them; the metaphysical stage, in which, while living beings are got rid of, certain abstract ideas, such as those involved in the words 'Nature,' 'Harmony,' and the like, take the place of thoughts as the productive causes of everything; and the positivist stage, in which all the different phenomena of the universe and the unseen spiritual agencies and abstractions, the mind grasps the notion of the universe in all its departments as proceeding according to certain laws or uniform sequences, to which the human mind is free to apply itself. This work was intended to apply this to the entire system of human knowledge. All that man knows, or can know, he says, consists of certain sciences which may be arranged in a hierarchical order as follows, according to the increasing specialty and complexity of the facts with which they respectively deal:—

1st. Mathematics, the most general and simple of all, which deals with the mere facts of number and magnitude; 2nd, Astronomy, which presupposes mathematics, but takes in the sciences of the celestial sphere, i.e., suns, planets, moons, comets, &c., as they are acted upon by the planets acting masses; 3rd, General Physics, which takes for granted the mathematical and astronomical laws, but concerns itself also with the motions and other mechanical phenomena of bodies on our earth; 4th, Chemistry, which, in like manner, presupposes all the foregoing, but investigates farther the phenomena of the molecular changes and constitution of bodies; 5th, Biology (subdivided into Vegetable and Animal), and involving Psychology as a department of Animal Biology connected with the general subject of the laws of growth and brain-function), undertaking the farther study of individual organised beings; and 6thly, Sociology or the Social Science, investigating, as the most complex phenomena of the universe, the intellectual and social activities of man, as their greatest object, under the name of positivism.

In 1848 M. Comte published a small mathematical work entitled 'Traité Elémentaire de Géometrie Analytique à deux dimensions,' followed not long afterwards by a popular treatise on astronomy, 'L'Univers.' The two books were admiringly received, and in 1844 he published as 'Discours sur l'Esprit Positif,' enforcing popularly the ideas of his larger work. Within the next few years, however, a second vital 'crisis' of philosophy was on the point of arising in the universities of the sentimental—work a certain change in his views. A virtuous affection, to which he makes frequent allusion in subsequent autobiographical passages in his prose, for a lady named Clotilde, whose death left him miserable, revealed to him, what Saint-Simon had long before hinted, the deficiency and meagreness of his philosophy on the sentimental and religious side. To make up this deficiency was the object of all his later activity. This he attempted to do, not by writing more positivist works, but by concentrating his thought and energy on the new problem of religion, with the fundamental doctrine of positivism; to accomplish which, seeing that positivism denies deity or invisible spirits of any kind apart from humanity, he makes humanity itself the object of the new worship. In 1848 he published a tract on the 'Religion positive,' in which the notion of the new religion, as the necessary appendix to his philosophy, was promulgated, and in 1849 he published a singular book of a more precise nature, entitled 'Culte Systematique de l'Humanite': Calendar Positivist, or System General de Commemoration publique, in which work he proposed a systematic worship by humanity of itself, as represented in its greatest men of all ages—twelve of whom he specified as worthy to preside over the twelve months of the year. This would be established on marriage ceremony and funeral rites when called upon by his disciples to do so. His disciples in this sense however were never numerous, and while publishing his last work, entitled '5th System of Positive Religion,' he supposed to have composed the last volume of his main work, 'Exposition de la Religion Universelle en ouvrage Entretiens Systematiques entre une Femme et un Pretre de l'Humanite,' which appeared in 1851 and the others have been issued since, he was not only in poor circumstances, but complained of the desertion of his pupils one after another, and expressed his sorrow that he saw no one all over the earth whom, before he died, he could ordain as his successor in the chair of the new philosophy and the pontificate of the new religion. M. Comte died Sept. 5, 1857.

Those who desire farther information respecting the life and work of this great man, will find it either in his own works above enumerated, or in two works published in this country presenting an abstract of his views—'Comte's Philosophy of the Sciences, being an Exposition of his Fifth System of Positivism,' by Miss Harriet Martineau, 'Positive Philosophy of Auguste Comte freely translated and condensed' (3 vols. 1853.) Comte's 'Philosophy of Mathematics,' extracted from his main work, has been translated in America by W. M. Gillespie; and his 'Popular Astronomy' also, if we mistake not, has found an English translator.

CONDAVIA, a genus of Plants belonging to the natural order Cichorieoideae. It has a campanulate calyx, 5-crenate or 6-toothed limb, deciduous; corolla filaments, with a somewhat curved tube, which is a little longer than the calyx, a dilated throat, and a 6-parted limb; stamens inserted above the middle of the tube or near the throat; anthers oblong, linear, bifid at the base, length of corolla; stigma ovate, cleft, 5-lobed; ovary sessile, middle of the cells. Seeds numerous, very small, wedge-shaped. The species are American shrubs, with 2-parted accuminate stipules and terminal many-flowered corymbs.

C. aequale is a native of the hills and ravines of the Peruvian Andes. It has ovate-oblong leaves, acuminate, cordate, sessile, pilate, coriaceous; coryzae large, bracteate, trichotomous; corolla purple externally, with the throat and filaments naked; teeth of the calyx broad, short, and broad with the tube; the tube is said to use this plant for adulterating samples of Cichoreum. Its bark is only slightly bitter, and may be easily recognised by its being white inside, rather bitter, and viscid.

C. alpino-americanum, a native of South America, and is used occasionally.

CONDEER, JOSIAH, was born in London on the 17th of
September, 1789. He was the son of a bookseller, and very early displayed a taste for literature. His first attempts were given to the world in the 'Athenaeum,' a monthly magazine then edited by W. Aikin, and in 1810, in connection with a few friends, a very small affair was published under the title of 'The Associate Minstrel.' In 1814, being at the time a publisher and bookseller in St. Paul's Churchyard, he purchased the 'Eclectic Review,' of which he continued to be editor for some time before he deserted the bookselling business in 1819. Under his management the 'Eclectic Review' received the assistance of many eminent men among the non-conformists, such as Robert Hall, John Foster, Dr. Chalmers, Dr. Vaughan, and others. During this period, his industry was taxed by the prodigious amount of books published under his superintendence. In 1824 also appeared 'The Star in the East,' a poem; and in 1834 'A Dictionary of Geography,' and a new translation of the 'Epistle to the Hebrews,' with Notes. In 1836 he edited 'The Congregational Hymn-Book,' issued under the sanction of the Congregational Union; and in 1837 he published 'The Choir and Oratory: Sacred Poems,' to which Mrs. Conder was a contributor. He was the author of many other works, but we have mentioned the principal.

Mr. Conder's reputation having become established among the Dissenters, he was requested in 1832 to undertake the editorship of 'The Patriot,' a newspaper recently established in the dissenting interest. From this time he took a more active part in public proceedings the Dissenters, attending their meetings, and affording the assistance of his counsels. The 'Patriot,' under Mr. Conder's management, became the organ of what may be termed in politics the Whig section of the Dissenters, as opposed to the Radical section under Dr. superintendent. For twenty-three years Mr. Conder fulfilled the duties of his office with exemplary care, industry, and liberality; producing also occasionally works of importance, such as 'Analytical and Comparative View of all the systems of Natural History, with Prophets, &c.,' and several pamphlets on stirring topics of the day.

Mr. Conder married in 1815 Joan Elizabeth, the daughter of Mr. Thomas of Southgate, by whom he left four sons and a daughter. After a short illness, he died on Dec. 27, 1855.

COUDE, JAMES FENIMORE, was born at Burlington, towards the tip; prebrachial and discal areole long, the latter closed near the posterior margin by a transverse vein; anal areole long, distinct, complete. Abdomen arched, rather long, with six segments more or less slender towards the base, outline of the base, rather stout; tubic very slightly curved, compressed and dilated at the tips, in some cases with a transverse suture; dorsal rather broad, opaque and onychia distinct.

CoUIN, a genus of plants belonging to the natural order Amentiferae. The species are small trees with imparipinnate leaves; islets alternate, unequal at the base, or oblique.

COOKSTOWN. [TYRONE.] COOPER, JAMES FENIMORE, was born at Burlington,
New Jersey, United States, on the 16th of September, 1789. His father was of a Buckinghamshire family, which emigrated to America about twenty years before; and his mother was a future novelist. When James was about two years old his father removed to the banks of the picturesque Otsego Lake, Western New York, and there founded the village of Cooperstown; and somewhat later he was elected a judge of the state of New York. He was admitted to the rudimentary branches of learning, he transferred himself to the care of the Rev. J. Ellison, an episcopal clergyman at Albany, by whom he was prepared for college. He remained at Yale college from 1802 to 1806, when, having discharged his military duty as he served at sea for six years, and his conduct won the approbation of his superiors, and the esteem of his fellow-officers. It was here he acquired that familiarity with a maritime life, and knowledge of the ports and phenomena of the ocean, which lend such a charm to his naval stories. On retiring from the service he in 1811 married Miss Delancy, a sister of Bishop Delancy of New York, and took up his abode in the family village of Cooperstown.

His next few years were spent in private life. It was not till 1821 that Mr. Cooper appeared as an author. His first work was a novel, "Precaution," which professed to be a story of English life. It met with no success, but the author, like most men of the time, proceeded to fore the public again, with "The Spy—a tale of the Neutral Ground." A thoroughly original and genuine American novel caught the American ear, much as "Waverley" had caught the Scottish. Its success was immediate and unbounded. In England its vivid picturesque characters and rapid movement gave it an additional charm of novelty, and Cooper at once took rank with the leading novelists of the day. The "Pioneers" followed in 1823, and confirmed the reputation of its author. A year later appeared "The Pilot—a Tale of the Sea." These were the types of a long series of novels which during many years flowed from Cooper's prolific pen. He had in them brought before his readers the mighty forests and wide prairies,—the backwoods of America, with their original occupants, the hunters and trappers, men who had never seen a city, and settlers, who were rapidly supplanting them; and the sea with its daring American privateers; and again and again he was to reproduce these in more or less varied forms. The strength of his narrative, his power in delineating character, his command of the passions, keenness of observation, and descriptive skill were acknowledged without stint, and America was admitted to have produced a great original novelist.

Like Scott, thought the tide of success was to be taken at the fall; and he published novel after novel with a rapidity rivalling that of the author of "Waverley." For a time his imagination and store of knowledge appeared to sustain without diminution the heavy drain. He was never hapless; he was a prolific and enterprising writer; his mind was like the reader along with more rapidity and interest, than in the "Prairie" and the "Last of the Mohicans," which appeared after "Lionel Lincoln" and one or two others, in 1836; in the "Red Rover" and the "Water Witch," and the "Wept of the Whig-Whisp," which followed in succeeding years. But in these and a few others he exhausted his genius, and novels like " Ned Myers," the "Sea Lions," "Merced p Cattails," "The Headman of Berne," served only to call into clearer notice the weak points of their author; yet the "Deerslayer" and one or two other of his later stories had so much of beauty and strength, that there had been no intervening failures, there would have been little reason to fancy that the hand of the great American novelist had lost its skill.

In 1829 Mr. Cooper visited Europe, where he remained for about ten years, his longest sojourns being made in London and Paris. The fruits of his European travel were the novels of "The Headman," "The Bravo," "Heidenmaier," and "Mercy p Cattails," which followed immediately after "Homeward Bound," and "Home as Found," which, with the "Introductory Letter to his Countrymen," stirred up some strong feeling. Nor was he, as we have already intimated, idle in the United States during the interval of his return to America, although in several of them he returned to his old American forests and sea haunts. But he wandered also often into the regions of home and foreign politics, not even keeping clear of controversy in his novels; and his very inaptitude for reasoning rendered him the more dogmatic in maintaining his own views and irascible under contradiction or dissent.

Some of his home critics he prosecuted for libel; his foreign opponents he denounced with unbowed wrath. However, he soon obtained his own, and was rewarded at home and abroad with a return of the old admiration and esteem; so that his death, which occurred at Cooperstown on the 14th of September, 1851, caused a general expression of sorrow throughout the country. He was buried in this country, where he had hardly fewer readers and admirers than in his own land.

Besides the novels mentioned above, Mr. Cooper wrote "The Pathfinder," "The Monikins," "The Two Admirals," "A Romance of Waverley," "Autobiography of a Pocket Handkerchief," "Castaways," "The Chainbearer," "The Crater," "Oak Openings," "Jack Tier," "The Sea Lions," and we believe one or two others. He also wrote "History of the United States Navy," which appeared in 1833; and a "History of the American Naval Officers," "Gleanings in Europe," "Sketches of Switzerland," "Notions of the Americans by a Travelling Bachelor," and "The Way of the Hour." Most European languages have translations of some of Cooper's novels, and it is stated that one or two of his Oriental tongues possess a version of at least one of his stories. Most of the earlier novels and several of the later have been rendered into German; and in French there is a translation by Delaunay, besides another in 6 vols. by Meens. Laroche and de Montémond.

COOT (Pulicaria).—COOTEHILL, county of Cavan, Ireland, a post-town and the seat of a Poor-Law Union, in the parish of Drumglen, about 10 miles S.E. of Enniskillen, and a prizetown founded in 1791. It is 7° 2’ W., 73 miles N.N.W. from Dublin. The population in 1851 was 2106, besides 1101 in the Union workhouse and other public institutions. Cootehill Poor-Law Union comprises 19 electoral districts with an area of 105,845, and a population of 44,333.

Cootehill lies on the road from Kingscourt to Clones, and has four principal streets, which are wide and substantially built. It contains a neat church, besides chapels for Roman Catholic and Protestant denominations. In the vicinity are a number of towns, and a large market for agricultural produce. The town stands at the western extremity of a series of lakes which are navigable for the greater part of the distance (7 miles) hence to Ballybay. The neighbours are well cultivated, and adorned with numerous demesnes and mansions. Quarter sessions for the county are held at Cootehill. There are here a bridewell, a dispensary, and a station of the constabulary force. A fair is held the first Friday in August.

COPLESTON, REV. EDWARD, D.D., was born February 2, 1776, at the rectory-house, Offwell, Devonshire. His father, the Rev. John Bradford Copleston, was the rector of that parish, and he educated at his own residence a limited number of poor children. In 1791—when he was 15 years old—he entered Jesus College, and in 1791 Edward Copleston was elected to a scholarship at Corpus Christi, Oxford; in 1793 he obtained the Chancellor's prize for a Latin poem; and in 1795 he was elected a Fellow of Oriel College. He obtained the Chancellor's prize for an English essay on 'Agriculture,' in 1796, and in 1797 was appointed college-tutor, though he had not then taken his degree of M.A. In 1803 he was elected Professor of Poetry to the university, in which office he succeeded Dr. Hardie. He published in 1813 the substance of the lecures which he delivered, under the title of 'Principles of Academical Education,' a work which gained him a high reputation for pure and elegant Latin composition combined with extensive poetical information. Some severe attacks on the University of Oxford having been made in the 'Edinburgh Review,' Mr. Copleston published in 1816 a 'Reply to the Calumnies of the Edinburgh Review against Oxford,' which was followed by another 'Reply' in the same year, and by a third in 1811. These replies were greatly esteemed by the university, and respectfully treated by the authors of the 'Calumnies.' Mr. Copleston was elected Provost of Oriel College, and soon afterwards the degree of D.D. was conferred upon him by diploma, the instrument setting forth that this distinction resulted from a grant made by one of the many public institutions which had recently conferred upon the University. Dr. Copleston is chiefly remembered as a divine by his work on 'Predestination,' which consists, for the most part, of three sermons preached at St. Mary's church, Oxford, 'An Enquiry into the Doctrines of Necessity and Predestination, with Notes,' and as the Appendix to the 17th Article of the Church of England.
Between the years 1811 and 1812 he contributed many articles to the 'Quarterly Review.' In 1816 Dr. Copleston was appointed to the deanery of Chester, and in 1827 he succeeded Dr. Summer in the bishopric of Dandoff and deanery of St. Paul's, London. He also held the honorary appointment of professor of ancient history to the Royal Academy of Arts, being a fellow of the Society of Antiquaries. After he became a bishop his time was chiefly occupied in the performance of the duties of his diocese. Some of his sermons, charges, and speeches in the House of Lords, were published at the time when made. His principal work as a bishop was 'Memoirs of E. Copleston, Bishop of Landaff, with Selections from his Diary and Correspondence,' 8vo, by William James Copleston, 1861, &c.

**COPROLITES** (Fr. coprolite), the fossilised excrement of reptiles, fish, and other animals, found in various strata of the earth. Dr. Buckland in his 'Bridge-water Treatise' first drew attention to the probable nature of these beds several of which had been previously known under the name of Bezoar Stones. These fossils were first detected in the Lias at Lyme Regis and in other localities, and their true nature inferred from the fact of their identity with similar masses found actually within the body of many species of reptiles and fishes. They are composed of scales of fishes, and occasionally teeth, and fragments of bone, belonging to species of fishes and reptiles which have been swallowed by the animal as food, and have passed undisgested through its stomach. They often occur in large numbers. These bones have been formed by the nodule-bearing excrement of some of the larger forms of recent fish, and have been accepted by comparative anatomists as indications of the nature of the intestinal tube in the extinct forms of Bezoar Stones.

Professor Liebig says in his 'Letters on Chemistry,' "in the autumn of 1842 Dr. Buckland pointed out to me a bed of Coprolites in the neighbourhood of Clifton, from half to one foot thick, inclosed in a limestone formation, extending as far as the eye could reach. This is an interesting example of copyright in the mineral kingdom of the Severn. The limestone marl of Lyme Regis consists for the most part of one fourth part of fossil excrements and bones. The same are abounding in the Lias of Batheaston, and Broadway Hill, near Evesham. Dr. Buckland mentions them in the midst of many places of a fourth part of Coprolites."

Coprolites, when chemically examined, are found to contain a large proportion of phosphate of lime. Liebig states that some he examined from Clifton contained about 16 per cent. of ash, and other specimens he examined afforded a much larger per centage. The occurrence of phosphate of lime in these substances has led to their use as manures, and large quantities are annually collected in this country. When prepared, it was found they were converted into the action of sulphuric acid, by which the phosphate is converted into a super-phosphate of lime.

Not only have the beds of the Lias afforded deposits of phosphate of lime which have received the name of Coprolites, but they have also been found in the Greensand, in the Wealden Formation, and in the Red Crag. In the latter formation it may be altogether doubted as to whether the phosphate of lime there found in the form of dark-brown or blackish smooth nodules, can be appropriately called Coprolites. These beads commonly occur in beds of the Red Crag of Suffolk, where, in the neighborhood of Ipswich and Woodbridge, and on the sea-coast of Felixstow and Bawdsey, it is worked to a considerable extent. In addition to the above various forms of Coprolites, there are of very various forms of Cataple, all of which contain large quantities of phosphate of lime, and are collected under the name of Coprolites. It is still a question of interest as to how the nodules not having an organic basis have been formed. It has been supposed they occur as deposits of lime derived from the destruction of organised beings, but it is very evident that phosphate of lime must have existed in some form or another before the creation of either vegetable or animal beings. The increase also of the number of species of species of fishes and animals demands that there should be some constant supply of this substance from the mineral kingdom. Whatever may be the result of further inquiry on this point, there can be little doubt of the improbity of calling all deposits of phosphate of lime Coprolites. A better general name and which is not exposed to the objection of a false theory would be Phosphatia. (Proc. Geol. Soc. London, 1847.)

**COPYHOlD.** The statute 4 & 5 Vict. c. 35, has been amended by the 6 & 7 Vict. c. 33; 7 & 8 Vict. c. 55; and 15 & 16 Vict. c. 51. The result of these statutes may be shortly stated thus. The lord may now be compelled by the tenant, under the penalty by a landlord, to purchase the beneficial use of his land at the first surrender and admittance which takes place, and on terms, if the parties cannot agree, to be fixed by the Copyhold Commissioners.

**COPYRIGHT.** In order to take advantage of any disposition which may be manifested by foreign nations to recognise British copyrights, powers have been conferred on the Sovereign, by the stat. 7 & 8 Vict. c. 12, to grant, by Order in Council, privileges of copyright in this country to the authors of books, prints, and works of art, first published abroad. The authorship of many new works is not of a manner to be granted to the authors of dramatic or musical compositions. Such Order in Council cannot, however, be made until due protection for British copyright has been secured to the subject of the country to the subjects of which the privileges of copyright in this country is conceded.

Under this Act, conventions for the mutual protection of copyrights have been entered into with the following countries: the United States of America and its Territories in 1848 and 1871; Prussia and Hanover, 1847; France, 1851; Anhalt-Bernburg, 1853; Hamburg, 1858; Belgium, 1858; Spain, 1857; and their stipulations have been embodied in the British statute 15 & 16 Vict. c. 12. Authorised translations of foreign books and dramatic pieces are by this statute protected for a term not exceeding five years from publication.

The Designs Act, 1850, confers rights to be provisionally registered for one year, and confers powers on the Board of Trade to extend the copyright for a term of three years. The same statute provides for the registration and protection against piracy of sculpture, models, copies, and casts. The British Design Acts have been combined with the foreign copyright Acts for the protection of work produced abroad under the statute 15 & 16 Vict. c. 12, to printe by lithography, or other process of indefinite multiplication. ['Blackstone's Commentaries,' Mr. Kerr's ed., vol. ii. pp. 416-417].

**CORACIAS.** [Roler.]

**CORALLINACEAE.** A family of Marine Plants belonging to the order Alga. According to Harvey's definition it includes the Corallinae and Spongistes of Kitting, and the Corallinidae and Nulliporidae of Dr. Johnston.

The forms referred to this family have been alternately regarded as Algal or Animal. While their structure was imperfectly understood they were regarded with many of the zoophytes (Polyphyllus and Polycon) and sponges as seaweeds. When the animal nature of these beings was established, it was found they were essentially marine plants, belonging to the animal kingdom. Recent researches have however demonstrated the truly vegetable nature of this family both in their general structure and mode of reproduction. The following is Dr. Harvey's diagnosis in his 'Manual of the British Marine Algae':—"Rigid, articulated, or crustaceous, mostly calcareous sea-weeds, purple when recent, fading on exposure to milk-white. Composed of closely-packed elongated cells or filaments, in which carbonate of lime is deposited in an organised form. Tetrasporae tufted, contained in involute or spherical conceptacles. Ceramidium furnished with a terminal pore.

The following general remarks on this family are taken from Dr. Harvey's work:—The root, where this organ is well developed, is an expanded connutaneous disc, often widely spreading. The frond almost always calcareous, efferveencing strongly when thrown into acids, rarely destitute of lime, very variable in aspect and habit. The lowest forms of the order are simple incrustations, spreading like the crustaceous lichens over the surface of rocks, or the fronds of the larger algae. In the smaller of these the crust is a mere film, as thin as paper, generally circular, and extending by means of small additions to the circumference, so that the frond becomes masked as it advances with concentric circles. In the larger the crust is thick and stony, rising by concentric laminae and sinuences and sinking into depressions. Still further advance manifests itself by the crust assuming a branched habit: at first papillate rise from the surface; these thickened, and widen, and lengthen, and throw out branches, till the shrubby front, of stony hardness, but extremely brittle, is..."
formed. All these changes in character take place within the limits of a single species, 

Corallina. Neary related to this (and by many botanists considered identical) is Muto-

phora, a genus in which the frond is expanded into leafy lobes, usually fan-shaped, sessile, or stalked, but not adnate to rocks; of a flexible substance, containing a smaller portion of carbonate of lime than the foregoing, and these have the habit of Padina, but differ from that genus in being of a red color. They are the most perfectly organised of the leafy or frondose Corallines (Millepora). The articulated or 

branchless Corallina, either smooth or red, consists, the branches formed of strings of calcareous articulations, truncafed at the upper extremity and rounded at the lower, each articulation connected with that above and below it by a flexible joint composed of cellular tissue, destitute of car-

cbonate of lime. It is difficult to say in which of these is the greater number they are heart-shaped or wedge-shaped, with the upper angles frequently prolonged with horns. 

The fructification consists of hollow external or immersed conceptacles containing a tuft of oblong spores, divided at maturity into four units. The whole 

ular, or in the same specimens, so that the determination of these plants is somewhat difficult. In many the articulations are cylindrical, in others oval and 

and irregular, but the greater number they are heart-shaped or wedge-shaped, with the upper angles frequently prolonged with horns.

4. **Hidenbrandia.** — The frond cartilagino-membranaceous (not stony), crustaceous, suborbicular, adhering by its lower surface; composed of very slender closely-packed vertical filaments; conceptacles immersed in the frond, orbicular, depressed, pierced by a hole, and containing tetratacospores and paraphyses at the base of the cavity.

**H. rubra** is found on smooth stones and pebbles between tide-marks and in deep water. It is very common, and forms a thin membranaceous crust, at first covered with mosses, and spreading concentrically, at last irregular in form, following the sinuosities of the body to which it may be attached. Viewed under the microscope, a small portion shows minute cells lying in a clear jelly. When in fruit, the structure is pierced by a hole which communicates with a chamber in which the spores lie. The colour is variable; now a bright, now a dull red.

Sub-order 3. (1) **Lithocystis.**

**Lithocystis.**—Plant calcareous, consisting of a single plane of cells, which are disposed in radiating dichotomous series, forming an appressed flabelliform frond. Named from a stone in the hamlet, because the cells have stony costs.

5. **L. Allmannii** is parasitical on *Chrysemnia clavellata* from an oyster-bed at Malahide, Dublin, by Professor Allmann. It forms minute dot-like patches of a whitish colour on the frond of the *Chrysemnia.* It is one of several fan-shaped fronds composed of quadrate cells disposed in dichotomous series. The plant is brittle, colourless, and effervescent in acid.

(Harvey, *British Algae.*); (Borley, *Ecological Mem.)

**CORBULA,** a genus of Marine *Mollusca,* belonging to the *Lamellibranchiata.* The shell is suborbicular or oval, tumid or depressed, very inequilateral, slightly inequilateral, rounded anteriorly, more or less truncated posteriorly, black prominent; surface of the valves more or less furrowed or transversely striated, covered with epidermis. Hinge composed of a recurved primary tooth in one or both valves, with corresponding sockets and ligamental pit beside it. Ligament small, triangular or kidney-shaped; muscular impressions slightly marked, united by a pallial o or very slight sinus. The animal is short, with very short united siphonal tubes. Orifices fimbriated. Mouth closed, except in front, where there is an opening for a hony narrow foot thick of considerable dimensions. Anal siphon with a conspicuous tubular membrane. Labial tentacles slender.

This genus was once abundant in the European seas, especially during the early part of the Tertiary epoch. Only a few species now exist. It has more species in the tropical seas of the present day.

C. nucleus is one of the most common species in the seas around the British Islands. Whilst very frequently found in the dredges, it is seldom washed on shore or found in shallow water. It is about half an inch in length and about one-fourth in breadth.

This genus belongs to De Blanchville's family Psilidae, which comprises *Solen, Panopea, Mya,* and other allied species. *[Psilidae.]*

CORBY. [London.]**

**CORCHORUS,** a genus of Plants belonging to the natural order *Tiliaceae.* The leaves of *C. olitorius* are used in Egypt as a pot-herb. Fishing-lines and nets, rice hags, and a coarse kind of linen called tap, are made in India of the fibres of *C. indicum.*

**CORDIA,** a genus of Plants belonging to the natural order *Cordiaceae.* It has a tubular calyx, 4-5 toothed. Corolla funnel-shaped or campanulate, with a flat 5-6-cleft limb, and a hairy or naked throat. Stamens 6, short, inserted in the throat of the corolla. Style protruding, bifid, with 4 stigmas. Ovary 3-4 celled. Drupe containing 1 stone with 1 or 3 cells, two of which are usually abortive.

**C. sativus** is a native of Hindostan. It has numerous species and varieties; the seeds bear edible and rubbery branches; the young shoots angular and smooth. The general height of trees ten or twelve years old about 20 feet. Leaves alternate, petiolate, round, coriaceous, and ovate, often slightly reaped; 3-nerved; of a hard texture, bright green above and pale underneath; from 3 to 7 or even 8 inches long, and rather less in breadth. Petioles nearly round and smooth. Panicles short, terminal, and lateral, roundish; the branches alternate, diverging, and one or more frequently dichotomous. Flowers numerous, small, white. Bracts minute, villous. Calyx villous, campanulate, leathery; mouth unequally toothed. Corolla short, campanulate. Segments 6, linear oblong; filaments as long as the segments of the corolla, and inserted immediately under their bases. Anthers oblong, fleshy, 4-cleft, with one ovule in each to the upper end of the axis. Style short. Stigma 4-cleft; segments long, rugose, and recurved. Drupe oblate-spheroidal, about an inch or an inch and a quarter in diameter; smooth when ripe, straw-coloured, and covered with a fleshy sarcotesta. Plums, Sebastos, or Sepiastr, two sorts of Indian fruit, have been employed as pectoral medicines, for which their mucilaginous qualities, combined with some salativity, have recommendation; they are believed to have been the *Peraeae* of Dioscorides. Linnaeus gives the name of Sebasten to an American species of this genus which is not known in medicine.

**C. Myxa** is a native of many parts of India, Persia, Arabia, and Egypt. It is of a larger size than *C. olitorius,* 4-5 feet high, and as thick or thicker than a man's body. The bark gray, cracked in various directions. Branches numerous, spreading, and bent in every possible direction, forming a dense shady head. The flowers are numerous, white, small; a very large proportion of them are sterile, and they always want the style. The drupe is glabrous, smooth, the size of a cherry, sitting in the enlarged calyx; when ripe, yellow; the pulp is almost transparent, very tough, and viscid. The fruit is of good quality, and the taste of the kernels like that of the filberts. It is the true Sebasten of the European Materia Medica. The fruits, according to Roxburgh, are not used in the Cireacis medicinally, but when ripe are eaten by the natives, and also most greenly in the tropical and sorts of birds, being of a sweetish taste. The wood is soft, and of little use except for fuel. It is reckoned one of the best kinds for kindling fire by friction, and is thought to have furnished the wood from which the Egyptians constructed their mummies. The wood is said or more by Dr. Royle to be accounted a mild tonic.

**C. Gresacanthus** is a native of the West Indies in woods, and of Mexico, near Acapulco. It has ovate oblong leaves, acute, quite entire, glabrous; racemes terminal, aggregate; flowers numerous; calyx ovate acute, glabrous; corolla 5-cleft; throat villous; stamina of the length of the corolla. This is esteemed one of the best timber-trees in Jamaica, of which it is a native. The wood is of a dark brown colour, and gently striated: it is tough and elastic, of a fine grain, and very worked. It is called Spanish Elm or Prince Wood by the English, and Bois de Chypre by the French.

**C. Rumphi** has brown wood beautifully veined with black, and small circular patches of the same.

There are above 100 species of this genus.

**CORDOVA,** the most important next to Buenos Ayres of the provinces of the Argentine Confederation, South America, comprehends the Sierra de Cordova and the surrounding country. It is divided into the N.E., N., and N.W. by the Grand Salina from Santiago, Catamarca, and Riojo, and on the W. by a travesía, or desert country overgrown with stunted prickly trees from San Juan. A sterile and thinly inhabited country lies on the south-east between the east and San Luis. On the south it extends to the Pampas of Buenos Ayres. The low sterile tract in which the rivers Segundo and Primero are lost, and the Lagunas Salados de los Porongos is situated, separates it from the country of Santa Fé. The province is variously estimated at from 65,000 to 90,000. Cordova is much more fertile than the countries which surround it. Numerous rivers descend from the Sierra de Cordova, but all are lost in the desert, except the Rio Tercero, which, during part of the year, finds its way to the Cercadilla, which falls into the Paraná near Santo Espiritu below Santa Fé. This river would be navigable for six or eight months in the year, but for two small rapids, which however might probably be removed. The country is divided into districts, and those which extend along their sides, have a fertile soil, and maize and fruits are raised there in abundance, but the plains, as well as the declivities of the mountains, are only fit for pasture. Cattle and sheep constitute the principal wealth of the republic. Hides and furs of llamas are exported to Buenos Ayres. At present the produce of this province is all sent to Buenos Ayres; but when steam navigation is established on the Paraná, the commercial intercourse will probably be largely carried on through Santa Fé. The province is ruled by a governor, assisted by a junta.
Cordoba, the capital, is situated in 31° 36' S. lat.; it is built on the banks of the Rio Primero, in a narrow valley considerably depressed below the general surface of the country. This situation is in many respects disadvantageous, but it is thus sheltered from the north wind, which blowing alternately on the higher grounds produces sudden changes in the atmosphere which are injurious to health. The town contains about 15,000 inhabitants. The streets are narrow, untidy, and the houses are built of brick, and better than in other towns in the interior; most of them have balconies. In the centre of the town is a spacious square, on one side of which is a neat town-hall, and on the other a fine cathedral. There are also ten other well-built churches and chieftly Moorish in style; and one modern church erected in a very costly manner. The University erected by the Jesuits is on a scale of great magnitude, covering an area of four acres. In former times it was famous, being the principal college (the Colegio Maximo) of the order in this part of the world. It contained also a very important library, which on the expulsion of the Jesuits was sent to Buenos Ayres. The university is still maintained, but is now hardly better than a provincial college. The city is intersected by two great and two smaller canals, and Franciscans. A fine public promenade occupies a considerable space; it includes a square sheet of water of about four acres supplied by a running stream, which is surrounded by walks, well shaded by trees, and has in the centre a large reservoir formed by the Segundo Guadalquivir. The town is in summer a shallow stream, but in winter becomes a deep and wide river; to preserve the town from the effects of its overflow a strong wall has been built, yet destructive floods still sometimes occur. Cordova was formerly the depot of the European merchandise intended to be sent to Peru, but this branch of commerce no longer exists. There is a mint in the town. The only manufacture is that of leather. There are no foreigners in the town, and scarcely any in the province. Religious toleration is unknown. AlicoGracia, a neat town near the base of the Sierra de Cordova, contains nearly 3000 inhabitants.

CORN CRAKE (Gammarirue). [RAILIID.] CORNEL TREE (Cornus.)

CORPUS CHRISTI, a genus of Animals belonging to the class Crustacea and the family Gammaridae. With the whole of the family it is remarkable for the length of its antennae. It has no claws. One of the species, C. tectile, is found in the English rivers. It was called C. tectilis by the old naturalists, and is well known on the coast of La Rochelle for its habit of burrowing in the sand. They live principally upon the annelids which inhabit the sand, and are remarkable for their great agility, the speed of their run being equalled only by that of the greyhounds. It is a valuable fish, and is frequently used as such. Another species, C. haematocheilus, is frequently caught in the east coast of the United States, and is used both for food and sport. It is remarkable for its great size, the length of the body and the number of its fins, being equalled only by the Porphyra.

Corporations. There has been a great increase of late years of bodies having many of the characteristics and privileges of Corporations, to which the remarks under Corporation in Penny Cyclopaedia, v. viii. p. 46, do not apply. In effect there are now three distinct species of Corporations—1. Those which may be described as existing at common law, having been generally created by Royal Charter. 2. Municipal Corporations. 3. Trading Corporations.

Under the first head may however be classed those Municipal Corporations by which the Municipal Corporations Reform Act does not apply, the universities and the colleges therein, and most of the old chartered bodies, such as the College of Physicians, the Companies of London and other cities, and many more of our ancient charitable institutions. These are governed by the provisions of their Charters and Bye-Laws, adherence thereto being enforced when necessary by the Queen's Bench or in Chancery.

The second class of the Municipal Corporations have been treated of in the chapter on Boroughs.

The third class, or Trading Corporations, comprises Railway and Canal Companies, and similar bodies, created by Act of Parliament, having commercial profit for their object. Thus Joint-Stock Companies for the purpose of banking or insurance are scattered abroad, by district, and, as each may be constituted according to the provisions of these Acts, and Other trading companies may constitute themselves into Corporations by registration in prescribed form, and on complying with certain requirements.

The distinctive ranks of these different kinds of Corporations are noted under the appropriate heads. [Joint-Stock Companies, § 2.]

CORREA, a genus of Plants belonging to the natural order of the Rutaceas, of which one of the species, C. albida, is used by the settlers in Australia as a substitute for tea.

CORRENTES, one of the Riverine provinces of the Argentine Confederation, South America, comprehends the territories which have been ceded to Paraguay, the provinces of Parana and Uruguay; the southern portion of the peninsula being occupied by the province ofEntre Rios. The population is about 30,000.

The southern and eastern parts of the province are somewhat mountainous, and by far the greater part is low. About half the surface is covered with timber-trees, much of the wood being available for house and ship-building. Some thousand square miles are covered with palm-trees, which are used for a great number of purposes. In the northern part of the province is the Laguna Vizcachas, which is in fact a vast marsh overflowed during the periodical risings of the Parana. It feeds all or nearly all the rivers which rise in the interior of the province and fall into the Parana except the one into or the Dominical and Matanzas rivers. In the latter the grass is generally sandy, but produces excellent crops. Cotton, tobacco, rice, sugar, indigo, and other tropical productions flourish, yet little attention is given to them, partly owing to the scantiness of the population and partly to the want of foreign markets. Besides the articles mentioned above, maize and barley, arrow-root, melons, sweet potatoes, and various tropical fruits are raised. The sugar-cane is at present only grown in order to extract molasses for distilling; the sugar consumed in the province is imported. The climate is healthy; the crops suffer at times from visitations of enormous swarms of sute and locusts, which entirely devastate the districts in which they appear. The chief employments of the inhabitants consist in the renting of cattle, the raising of sugar-cane and other crops, and in the cultivation of good pasture land. Sheep however do not thrive very well. Large numbers of hides are exported. Mechanical pursuits are entirely neglected. The province is well adapted for commerce, there being on the Parana four wharfs which serve as good ports, and three on the Uruguay. The opening of these rivers will doubtless prove of great benefit to Corrientes, but the traffic can only be fairly developed when the rivers are navigated by steam-vessels. The inhabitants are for the most part a mixed race of Indians and Spaniards, although the latter form by far the greater portion of the population. There is a great amount of trade among the different tribes of Indians, and the latter enjoy great freedom of movement. The women and children are larger than the men. They do a good deal of the agricultural labour, as ploughing, hoeing and attending to the crops, and reaping; make cheese for sale as well as home consumption; the men, however, escape to Buenos Ayres to buy cotton and woolen cloths for summer and winter garments.

The government is almost entirely in the hands of a governor, who is elected by the Congress for a term of three years. The Congress consists of 10 deputies,—one from each of the 14 departments, except La Plata, which returns two deputies. The revenue is derived chiefly from customs duties, and the church property which was seized by government during the civil wars. The army consists in time of peace of 1000 men, but during war all males are liable to military service. The civil power is vested in the three judges; and, during the late war with Buenos Ayres a reserve corps of 900 or 1000 men mounted on horseback, who are said to have proved of great service in some engagements with the enemy. The inhabitants of Corrientes, who number about 10,000, are of the most peaceable dispositions; their only manner of entrance into the engagements with Buenos Ayres is by the opening of the navigation of these rivers a leading object in all negotiations. The army of Rossa was defeated Feb. 1481, by the army under General Urquiza, the governor of Corrientes, who mounted himself on horseback, and proceeded on board a British steam-vessel to England.
Coryphodon is a genus of Fossil Animals belonging to the family of Tapirs. The remains of this genus have been found in this country; and although closely allied to the genus Lophiodon of Courier, Professor Owen regards its distinctive characters as sufficient to separate it from that type. The specimen on which this genus was established is unique, and was dredged up from the bottom of the sea between St. Osyth and Harwich on the Essex coast, and now forms part of the collection of the Kent, Essex, and Hants Natural History Society.

The specimen is petrified, containing metallic salts and having the appearance of fossils from the London Clay. There is little doubt that it was originally imbedded in the Eocene Tertiary formation of the south coast of England of which it forms a part of the lower jaw, containing the last and part of the penultimate molar teeth of the lower jaw. Although this fragment resembles the same bone in the genus Lophiodon, yet a closer examination of the crown of the last molar tooth exhibits a smaller anterior-posterior diameter in proportion to its transverse diameter, as compared with the corresponding tooth in that genus. It also differs from the teeth of Anthracotherium, to which it has some resemblance. Professor Owen infers from this and other characters of these teeth that 'the whole dental series of the extinct Eocene Pachyderms offered modifications of the Lophiodont type of dentition, which led to that of the Anthracotherium, more especially of the smaller species from Garamo and Valely. From the Eocene horizon of Panama, Professor Owen believes to constitute a new sub-genus, the Anthracotherium, which has been described from specimens of that term. The genus Coryphodon, which I have proposed for this sub-genus, is derived from corrus, a point, and mori, a tooth; and is significant of the development of the ridges into points. The broad ridged and pointed inner surface of the tooth indicates its adaptation to accommodate the coarser kinds of vegetable substances; and it is very probable that the habits and food of the Tapir, which is the nearest existing analog of the Coryphodon, are not very different from those of the 'ancient animal of the last molar tooth of the lower jaw. The name Coryphodon, which I have proposed for this sub-genus, is derived from corrus, a point, and mori, a tooth; and is significant of the development of the ridges into points. The broad ridged and pointed inner surface of the tooth indicates its adaptation to accommodate the coarser kinds of vegetable substances; and it is very probable that the habits and food of the Tapir, which is the nearest existing analog of the Coryphodon, are not very different from those of the 'ancient animal of the last molar tooth of the lower jaw.' **navigation** of those rivers, thus enabling the produce of the republic to be shipped at the port of San Juan de Nicaragua, though it lies some 200 miles down the river on its lower course. The Estrella, the Arena, and the Baranca are among the more important. Several small lakes occur on the tableland.

**Climate, Soil, and Productions.**—The climate of Costa Rica is on the whole more regular and healthy than in other parts of Central America. There are two seasons, a dry season, which commences in November and lasts until April, and a wet season which occupies the remainder of the year. The climate is frequently oppressively hot, but more frequently is very healthy. In the rainy season thunderstorms of a very severe description are frequent.

The soil is of varied quality, but in many parts very fertile. On the most elevated districts there is a thin soil, and the soil descends, especially along the eastern coast, they are very abundant. A good deal of timber, especially Brazil wood, mahogany, and cedar is exported.

Around the town of Cartago and on the western and northwestern parts of the country, wheat is cultivated to some extent. Maize is grown much more extensively, and is exported somewhat largely to Chili and Peru. Corn is however the staple; it is of fine quality, and meets with a ready sale. Tobacco is raised to some extent on the table-land both for home consumption and for export. Sugar is an important article in the agriculture of Costa Rica; it is chiefly grown on the western side of the country, and exported from Puntá de Arenas. Cacao, indigo, &c., are also grown. All the chief interfluves or passes are producing abundantly except cotton, the vine, and cochineal, which are destroyed by the heavy rains. Agriculture however, though it is upon its agricultural produce that Costa Rica is chiefly dependent, is in a very backward state, and the capabilities of the soil are very far from having been made fully available.

The most common fruits are apples, pears, peaches, &c.; the vegetables the leguminous kinds, as peas, beans, lentils, &c., are the most common. There are some good pasture lands, and along the San Juan cattle forms an important part of the wealth of the country. Horses and mules are bred, but not in large numbers. Swine are raised in the low districts. Sheep are tolerably abundant on the table-land. Poultry are bred in great numbers.

Fish are very plentiful along the coasts and in the rivers. In the Gulf of Nicoya pears and the pearl-shells are obtained; also a shell-fish which yields a purple dye.

Several metals are said to exist, but gold is the only one which is worked. The most important gold mines are those of Aquacut not far from the gulf of Nicoya and Real del Monte. Coal is reported to have been found, but it is not worked.

The manufactures are confined to the coarse articles of home consumption. They consist chiefly of coarse cotton goods, common hats, coarse earthenware, furniture, wooden utensils, &c. The commerce appears to be steadily increasing.

The exports consist of coffee, of which about 16,000 cwts. are exported annually; hides, about 10,000 annually; with mahogany, cedar, Nicaragua wood, sarsaparilla, mother-of-pearl, and a small quantity of pearls. Grain, fruit, drugs, cattle, and poultry, and various miscellaneous articles likewise form a part of the exports. The total annual value is estimated at upwards of a million dollars. The imports amount in value to about three-fourths of the exports. The exports are chiefly made in British vessels. All the shipments are made from the Pacific ports, and mostly from Puntá de Arenas. The imports nearly all reach the northern states of Central America, Chili, Peru, and the West Indies. The imports from Great Britain consist principally of cotton goods, woollens, hardware, and other dry goods. Ccrapes and other China goods are brought largely in American vessels, as well as coarse stuffs. Silks, brandies, and trinkets are brought from France; wines from Spain. A commercial treaty was made with England in 1850.

**Agriculture.**—Costa Rica is divided into six departments—San José, Cartago, Guanacaste, Alajuela, Guanacaste, and Puntá de Arenas. The only towns of any importance are the capital, San José; Cartago, the former capital; and Alajuela and Villa Vieja on the western coast.

**San José,** the capital of the republic, population about 16,000, stands on the elevated table-land, 9° 46' N. lat., 84° W. long. Its site is said to be 4500 feet above the level of the sea.

It is a modern city, having grown up since the declaration of independence. It is the seat of the legislature, and courts of justice, as well as of the bishop, it has no buildings of any beauty or importance. It is however a busy commercial town. It communicates by a cart-road 72 miles long with its port, Puntá de Arenas, which is a thriving place, being the principal port of Costa Rica.

**Cartago stands at the base of the Volcano of Cartago,** about 16 miles E. by S. from San José; population about 6000. It was once the capital of Costa Rica, and of the great and splendid archbishopric. It has since been gradually neglected as well as political consequence, but in both respects it has given way to San José. In 1841 it was almost entirely ruined by an earthquake, which destroyed seven out of its eight churches and nearly 9000 houses. It has since been reconstructed, and its population is now about 10,000, stands nearly midway between San José and Puntá de Arenas, and is a place of some trade. A good deal of sugar is raised in the vicinity. Villas Vieja about 7 miles W. from San José, is likewise a place of some trade.

**Curridabat,** Asaari, Paraíso, Heredia, Barba, and Esparaz, are other towns of more or less consequence.

**Government.**—The government is in the hands of a president, elected for six years, and the assembly consisting of 12 deputies elected for three years. The chief court of justice is the Tribunal of San José, which is presided over by seven judges. The militia consists of 5000 men, of whom 200 are called upon at a time to form the army on duty.

During the Spanish occupation of this part of America, Costa Rica formed a part of the kingdom of Guatemala. After the declaration of independence by the Spanish American colonies, September 15, 1821, it remained for a short time united to the Mexican kingdom of Turib; but when the new federal union of the United States of Central America was established in 1823 after the model of the United States of North America, it formed one of the united states. On the dissolution of this short-lived union, Costa Rica declared itself an independent republic, and has so continued ever since.

**COTARJINNA. [CHEMISTRY, S. 1.]** COST, MANUFACTURE OF. London, Liverpool, and Glasgow, are the three great centres into this country, especially Liverpool; and the amount of this import is truly marvellous. Liverpool and Manchester often take opposite views of the cotton trade; they stand to each other in the relation of seller and buyer in respect to this commodity; and their interests frequently lead in opposite directions; but no such difference can affect the real magnitude of the trade. When we consider that Lancashire now contains nearly two millions of souls, that the Glasgow district contains seven hundred thousand, that the Yorkshire contains about two millions, and that the whole extent of the cotton manufacture includes these districts, and that Cheshire and Yorkshire, together with other counties, also contain their hundreds of thousands of cotton-workers—we can hardly fail to see how extremely important the regular supply of cotton must be to Great Britain.

In our previous article (vol. vii. p. 93) we have brought down the statistics of the supply of this important article to 1835. The vast increase of our manufactures has of course meant a vast increase in the demand for larger and better material for which the United States of America are still our chief source, and on the whole it is the best, the cheapest, and the most reliable. But the British manufacturer does not like to purchase foreign material, and this, particularly for a crop which is so likely to be affected by seasons, and of which the cultivation, which is by slave labour, he apprehends may be some day suddenly interrupted
For many years he has been looking out for places where a future supply may be looked for. But our East India possessions, Brazil, and Egypt (which is made to include Syria and a few other districts of the Mediterranean coast of Asia) have long furnished a portion of his material, but by no means enough to satisfy his wants. The cultivation of cotton has of late years, in the Sudan, in West Africa, and in the Cape of Good Hope, the West India Islands, and Guyana, among our own settlements; and recently Dr. Livingstone has stated the probability of obtaining a large supply from the interior of Africa with a likelihood at the same time of supplanting the slave-trade by occupying the natives in useful and profitable industry, instead of their barbarous and predatory wars. This, if ever realised, must evidently be a work of time. In our own settlements the price of labour seems on the whole to have increased to an amount considerable of the quantities we derive from thence; for though there has been a general increase, the supply is very irregular, and is not large. In the year 1856 the United States supplied 77 per cent, the British possessions 17, Brazil 21, Egypt 32, and other places 6 per cent. of the total quantities imported. A portion, varying from one-sixth to one-seventeenth, is re-exported in the raw state, for most of the European nations are competitors with ourselves in the cotton markets of the world. Hamburg, Amsterdam, Rotterdam, Trieste, Antwerp, and France (chiefly at Havre) collectively take about two-sevenths of the quantity imported into the United Kingdom. A part of this, as we have said, is sent from England, but on the other hand there is every year imported a quantity of cotton manufactures, chiefly as East India goods, stockings, fringe, yarns, &c., to the value of about 1,500,000L., which has not been included in the following statement of the import of raw material, and the declared value of exports from the year 1856 inclusive. We have given occasionally a statement of the sources whence the raw material is derived, as they show the enormous differences of the crops in different places, and sometimes that an insufficient supply from America has been in some measure made up by our considerable imports from Europe, especially from our own possessions; but we have not thought it necessary to repeat it for every year.

Here was a large falling-off everywhere except in the British possessions, and in "other places," showing the efforts made to procure the raw material. Probably a portion was obtained from the confiscated south sea islands, and from the alluvial deposits of the Nile, but they are not mentioned as manufactures, however, do not appear to have suffered. The following year shows a large increase from the British possessions:

In this year the importations from Egypt, which had been gradually declining, sank to 127,160 lbs., but rose the next year to 8½ millions, and in 1846 to 11½ millions.

In the year 1857, the duty on raw cotton was taken off, but from a deficient supply the manufacture declined, as also in the following year; nor did it recover itself till 1849.

Here are the figures for cotton vary greatly. Different countries, different years, different qualities in the same year, all lead to difference of price. Sea Island cotton always realises the best price, while Sumatra cotton is in this list; 1849 was a cheap year, while 1850 was a dear year; the lowest Sea Island (in the beginning of Oct. 1850) was quoted at 8½ per lb., while the highest reached 24½, and the average was 12½. As the very dear cottons are sold only in small quantity, the average price for 1849 was probably about 6½ per lb., and for 1850 about 8½. We give the prices varied at periods, ten years apart, with the latest prices of the so-called Orleans for America, and Perambuco for Brazil:—

</table>

At the same period there were 41,290 bales, chiefly East Indian, in stock in London; and 10,920 in Glasgow, making a total of 422,710 bales.

The quantity of cotton used in the mills of this country does not always show the quantity of work done. The quantity thus consumed was enormously greater in 1848 than in 1847, and a little greater still in 1846; but the quantities of work done, and wages paid, did not increase in a similar ratio. The latter two elements depend in great measure on the weight of cotton used in making a particular size of cloth or yarn. In some states of the market, heavy goods pay the manufacturer better than those of lighter texture; and at such a time the consumption of cotton is increased, though neither the manufacturers' profits nor the workmen's wages may have reached a higher aggregate. In some cotton fabrics the latter element is predominant in the whole value; in others it amounts only to one-fifteenth; in those exceptional cases; and between them every kind of ratio is observable in some or other of the numerous varieties of manufacture. In the case of yarns, the material is worth three-fourths of the whole price in some specimens, and only one-twelfth in others. A given number of spindles, employed in making cotton twist of the thickness called No. 20, would use up 1340 lbs. of cotton, in the time which would elapse in producing No. 30 out of 840 lbs., No. 40 out of 580 lbs., and No. 60 out of 224 lbs.; in the high Nos. the relative value of the labour is higher, and consequently the relative value of the material lower, than in the low Nos. In some of the gigantic cotton mills 30,000 or 40,000 lbs. of cotton less will be used in some weeks than in other weeks to turn out the same total length of yarn. The machinery and all the hands may be employed at both periods; the difference arising from fine light goods being made at one time, and coarse heavier goods at another. When the demand for printed muslins and other light goods is less than that of domestic or coarse cotton goods, the consumption of cotton in England is found to lessen. An advance in the price of cotton is much more strongly felt in respect to coarse goods and yarns, than in fine; so much so, indeed, that the demand from many manufacturers in the home market is cut down, if the price fluctuates beyond its usual limits; whereas in light goods, wherein labour forms a large ratio of the selling price, a rise in the price of the raw material is not so sensibly felt. Whenever the supply is deficient and the price high, the manufacturer has an inducement to produce light goods instead of heavy; and for a like reason, when the demand is slack, there is less dead weight of such capital in a stock of light goods than of heavy goods of equal market value.

The argument put forth to show that we ought not to continue to be so much dependent, as we now are, on the United States for our supply of cotton, are somewhat as follows:—That our yearly supply from other quarters has been gradually decreasing; that the price of cotton is now and is likely to be more variable for consumption increases in a less ratio, so that it can only be kept up by encroaching on the reserve store; that the United States is the only country where the growth of cotton is materially on the increase, and this increase is not equal in rapidity to the increase in heavy manufacturing or consuming power in Europe and the United States; that no stimulus of price can materially augment the increase of supply in the United States, since the planters always grow as much cotton as the negro population can pick; and consequently, if the cotton manufacture of this country is to increase, it can only do so by applying a great stimulus to the growth of cotton in other countries adapted to the culture.

While these "other countries" are to be, is a question whereon much difference of opinion prevails. In the early stages of the cotton manufacture, the countries surrounding the Mediterranean furnished us with nearly our whole supply. In the 18th century the West Indies provided the chief cotton supply; but at present the Mediterranean and the West Indies combined furnish a very insignificant ratio. Brazil, Egypt, and India, have successively entered the market; Australia and South Africa have recently done the same; and the question arises, which of these countries will furnish a supply which will materially lessen our dependence on the United States? The Manchester authorities themselves are at issue on this matter; for while some point to the East Indies as the source of an inexhaustible supply, others feel reliance on our own colonies in the West Indies, Africa, and Australia.

Since 1835 there have been no inventions to alter materially the processes of manufacture in cotton, but the improvements in the machines have greatly facilitated the production in most of the various branches both of weaving and printing.
the parties consent in writing, claims to any amount may be
be brought. (Blackstone's Commentaries, Mr. Kerr's edition, vol. viii, p. 136.)

On the motion of the Crown for the issue of an ordinary action (16 & 17 Vict. c. 107). Questions between the Crown and any party liable for Succession Duties (not exceeding fifty pounds) may also be determined in this Court; the decision of the judge in such cases also being final (16 & 17 Vict. c. 107).

The County Courts are essentially local courts, for to give jurisdiction the defendant must reside within the district of the court, at the time of the action being brought. By leave of the Court, however, an action may be brought where the same thereof arose within the district of the Court, in cases in which the defendant or one of several defendants has dwelt or carried on business in such district within six months. The Court has also jurisdiction to give a landlord possession of his land to be sold. The officers of the Court, so far as they are necessary in the administration of the Court, are elected annually, and no fine has been paid, where the tenant's term has determined, or he has received notice to quit, or where the rent is half a year in arrear.

If jurisdiction in this century is explained elsewhere (Ch.2). The County Court has an exclusive jurisdiction in determining the claims and disputes of the members and officers of Friendly Societies, Industrial and Provident Societies, and of Literary and Scientific Institutions (18 & 19 Vict. c. 265). His Excellency the Governor of the Colony, and in the appointment of trustees to, and in the regulation of, all charities within the district of the Court, of which the gross annual revenue does not exceed 30£. [Charters, S. 2.]

A society owning land may, in the name of the office of the County Court, which sets out the names of the plaintiffs and defendant, and the nature of the action. Thereupon a summons is issued, a copy of which is served on the defendant by one of the bailiffs of the Court, requiring the defendant to appear, which he may do, if he is at the Court in which he is summoned, or have judgment given against him. If defence is made, the matter in dispute is, on the trial, inquired into, and disposed of summarily by the judge, who is to decide all questions, as well of the title as of the action in which he is summoned, and to determine a jury for the trial of matters of fact; for in actions for sums above 50£, a jury of five may be obtained as of right; in this case the facts are to be tried by the jury.

In actions for more than 50£, an appeal lies to either of the sessions of the court in which the action is tried, and the decision of the judge in matter of law, or in the reception or rejection of evidence. No appeal lies against his decision in matters of fact.

The Court, which is held once a month, is a court of record. On its judgment execution may be issued against the goods of the unsuccessful party. If he has nogoods, but has the means of paying, and refuses to do so, he may be punished, after inquiry into his circumstances, by imprisonment for a period not exceeding forty days; or the judgment (if for more than 50£) may be recovered as of the superior courts, and enforced there by the ordinary process of execution.

To encourage suitors to resort to this Court, the plaintiff in the superior courts (in suits in which they have concurrent jurisdiction with the County Court) and the defendant, where he recovers less than 50£, and in actions of tort where he recovers no more than 50£, unless the judge who tries the case certifies for costs, or it appears that there was sufficient reason for bringing the action in the superior court. Previous to the passing of this Act (1883), the Courts of Bankruptcy had, by the statutes 5 & 6 Vict. c. 116, and 7 & 8 Vict. c. 96, called usually the 'Protection Acts,' jurisdiction to grant to any person who was a trader owing less than 100£, in all, or who was so a trader within the bankrupt court, an order upon the bankrupt for the recovery of goods. This jurisdiction was, by the statute 10 & 11 Vict. c. 102, vested in the County Court, and the Court for the Relief of Inebriate Debtors, in London. [Parochial Acts, S. 2.] In the County Court, also, may now be tried all actions of replevin. [Hartshorn, S. 2.]

The judge has also power to grant a warrant for the arrest of an absconding debtor, and by statute 17 and 18 Vict. c. 104, to direct a vessel which has caused injury by collision or other fault to be arrested at any port for the injury, or security given to abide the event of legal proceedings.

The nature and jurisdiction of this Court have been described thus fully, in giving the course of the recent erection of these tribunals, but of the extent and variety of the powers vested in them, and the important position they have taken in the estimation of the people. (Blackstone's Commentaries, Mr. Kerr's edition, vol. viii, p. 136.)

The Courts of Convenience, anticipated in this article on the subject ('Penny Cyclopedia,' vol. viii, p. 115), took place in 1846, in the re-organisation of the County Courts, with a simple and inexpensive procedure, and a professional judge in lieu of the Sheriff and Justices of the peace.

The County Court, has also been abolished, and provision made for the surrender of the inferior local courts by corporations and the lords of manors and hundreds. Most of these indeed have long been as much in desuetude as the court of piepouidea. Many of the more important borough courts have however obtained a renewed vitality, by having the provisions of the Common Law Procedure Act of 1853 and 1854 extended to them, by order in Council. This has, of course, produced some anomalies. An instance is the trial of Liverpool & Manchester Bank, brought annually before a jury, who in the absence of the Board himself commanded to enter an appearance at Westminster by the Queen; obliged to obey a like order to appear at Lancaster by the Duchess of Lancaster; threatened with judgment for non-appearance by the Mayor of Liverpool, if he fail to appear at the Court which, as it befits his rank, he is required to answer a plaint in the County Court of Lancashire holden at Liverpool. As to the alterations which have been made in the jurisdiction of other courts, see BANKRUPT, S. 2; EQUIT, S. 2; Psoar, S. 2; Divorc, S. 2.

COWPER, EDWARD, was born in 1756. Little or nothing has been published concerning the circumstances and events of the early life of this distinguished inventor and improver of machinery. It is known however that it was while working on his invention that it was observed that Mr. Applegate was induced to build the extensive printing-office in Duke-street, adjoining to Stamford-street, London, now occupied by Messrs. Clowes, and he was a partner with Mr. Applegate in that establishment. They were also connected in making machines for calico-printing, and in the construction of new machinery for printing the 'Times,' of which, in conjunction with Mr. Applegate, he published a description. In fact, some of the most important improvements in the apparatus and machinery of the invention, such especially as the giving a diagonal action to the rollers on the self-acting inking-tubs. In the Great Exhibition of 1851 he exhibited a model, made by T. B. Winter, a student in King's College, London, of the printing-machine now in general use. Many of the improvements in the Great Exhibition were printed. He had for many years an engagement at the large blacking-factory of Messrs. Day and Martin, in printing their labels in such a manner as to defy imitation. He furnished some contributions to the 'Penny Cyclopedia,' one of which was an elaborate article on a 'Button.'

Mr. Cowper, during some of the later years of his life, was professor of mechanics and manufacturing arts at King's College, and it is as a lecturer that he was best known to the public. His course of imparting knowledge consisted not only in giving descriptions, and illustrating them by models, but in exhibiting the machines themselves, and showing them at work. His manner of lecturing was simply and popular, and he had always a full attendance. His knowledge of machinery, of mechanical construction, and the mechanical arts, embued the most minute as well as the largest objects. He delivered lectures on the mechanical structure of the Crystal Palace of 1851. He was much respected for his inventiveness, and his words are so rich in language, so full of economy, so full of mental principles, and so sound in thinking, that his ideas are rich in substance; partly a德尔挖掘机, partly a rudely aggregated deposit of
sand, shells, pebbles, and bones. To these divisions, whose origin is due to different local conditions, and successive times, Mr. Crawford added that of Coraline Grag, and Mammaliferous Grag. The position of theseheads will be best seen from the following table of the classification of the Tertiary Rocks from Professor Aasted's 'Elementary Geology.'

Newer Tertiary, or Pliocene Series:
1. Lower Gravel and Sand.
2. Till.
Middle Tertiary, or Miocene Series:

CRANBROOK. (Kern.)

CRASSULA, a genus of plants, the type of the natural order Crassulaceae. It has a 6-parted calyx, much shorter than the corolla; sepals flatish; the petals 5, stellate, spreading, distinct; the stamens 5, filaments awl-shaped; the scales 5, ovate, short; carpels 5, many-seeded. The species are very numerous. They are succulent herbs or shrubs, and are mostly natives of the Cape of Good Hope. Their leaves are opposite and entire, or nearly so. The flow- ers are mostly white, but some are yellow, if not coloured. Of the fifty species that have been described, and of many of them, on account of their grotesque appearance, are cultivated in our gardens. They are greenhouse plants. One species, C. tetragonos, is used in making a W.Hope as a remedy in dysentery. Any medicinal properties they possess is probably owing to the presence of tannin.

CRAWFORD, THOMAS, an eminent American sculptor, was born at New York on the 22nd of March, 1813. At school he obtained some acquaintance with Greek and Latin literature, but, as is frequently the case with youths in his country, he seems to have been allowed in early life to follow very much his own course. Like Chantray, his earliest instructor, the chisel was a carver in wood. Whilst with him however his strong desire for higher training began to develop itself. He formed a collection of casts of ancient and modern works of a high class, and he learnt to model in clay. At length he was placed as a pupil under Mesmer, Frazee and Lannitz, and entered as a student the academy of design in New York. Mr. Lannitz urged him to proceed to Rome, and gave him a letter of introduction to Thorwaldsen. Accordingly he proceeded to Italy in 1834, and was received into the studio of Thorwaldsen, to whose friendship he was greatly indebted. Thrown by the death of his father on his own resources, he for some time supported himself by making busts. The first poetical work of his which attracted particular attention, was the statue of Orpheus, destined by Thorwaldsen to a place among the statues of the great men of past ages. The statue was never finished by an attack of brain-fever, the precursor of his premature fate. On his recovery he completed the Orpheus in marble, a commission having during his illness arrived for it from the Boston Athenæum. It excited general admiration and anticipation. He worked on diligently, gaining in executive skill and confidence, and rising steadily in reputation.

Among the chief of his earlier works are his 'Herodias' with the head of John the Baptist; 'The Babes in the Wood;' 'Flora;' and 'The Dancers'—two life-size statues of children, which have had considerable popularity. Among the best of his later works are his bronze statue of Beethoven, now in the Athenæum at Boston, America; the equestrian statue of Washington, which stands in the square at Richmond, Virginia; and the more ambitious allitoilevls of the 'Progress of Civilisation in America,' which he was commissioned by the federal government to execute for the pediment of the Capitol at Washington. Others of his works are his statues of the Dean of St. Paul's, A Shepherdess; 'David;' and 'Prayer;' his groups of 'Adam and Eve,' of heroic size; 'A Family suffering under the plague of Flies Sarpent;' 'The Baby attempting to save herself and Child from the Deluge;' and his ideal busts of Sappho, Vesta, &c. He also made numerous designs for bas-reliefs: Illustrative of the Old and New Testaments; the poets of Greece, Italy, and England; events of American history, &c., as well as several models of leading American statesmen.

For a short time after entering Rome, Crawford made that city his home. He had just completed a new and spacious studio, in order to work with more convenience at the numerous commissions which awaited completion, when he was stricken with a disease—tumour on the brain—which rendered him unable to perform his work. To the care and attention he received from the learned and humane French and Italian doctors he owed the benefit of medical advice, but failed to obtain relief, and died in London on the 8th of October, 1857. Crawford was a sculptor of a very high order of merit, not reaching to the first rank, but coming close to it. His works display originality rather than refinement, or power rather than technical skill. Casts of some of his statues are in the Crystal Palace at Sydenham.

CREA. [Ralliaed.]

CREWE, Cheshire, a town in the parish of Coppenhall and hundred of Nantwich, is situated in 53° 6' N. lat., 2° 56' W. long. In 1891 the census gives the population of the town to be 6,896, and the population of the town and its suburbs 13,076, or 11,61 miles square. The town is on the Grand Junction Railway, the branch to the town being opened in 1851.

The town of Crewe owes its erection entirely to the formation of the London and North-Western line of railway. The inhabitants consist chiefly of persons in the employment of the railway company, with their families. The houses and shops are well built; the streets are wide, and the footpaths are laid with asphalt. The town is lighted with gas, and well supplied with water, a powerful steam-pump supplying at one time the engines in the extensive workshops of the company, and the waterworks are under the management of the railway company. The water is intended to be used by the inhabitants passes through two filtering processes before reaching the houses. Bathhouses are also provided at a cheap rate. The town of Crewe has a council for the management of the affairs of the community. The members of this council are elected by the workmen and inhabitants, and one-third by the directors of the railway company. A church has been erected by the company: the Wesleyan, Primitive, and New Connexion Methodists, Independents, Scotch Presbyterians, Baptists, and Roman Catholics have places of worship. Schools are held for boys, girls, and infants have been provided by the company, and a library and a mechanics' institute are supported by subscription. Medical attendance and medicine are secured for the workmen and their families on payment of a small weekly rate, the highest charge (that for a married man with a family) being 2d. per week. A field in the neighbourhood is used for cricket-playing. The railway station at Crewe is very spacious. From this place branch off five lines of railway, affording ready means of communication with all parts of the country. The workshops and machinery of the North Western Railway Company at Crewe are on a very extensive scale. Railway carriages and locomotive engines are mass manufactured and repaired. The number of carriages of all kinds maintained at Crewe amounts to about 700, of which 100 are at a time usually under repair. Crewe Hall, the seat of Lord Crewe, is in Crewe township, about one mile from the railway station.

CRISEUS, a Thracian king. [Herod. ii. 8, 29; Steph. Byz.]

CRISTIANS, a race of men, who were first discovered by the Portuguese, in the 15th century; they inhabit the island of Madagascar, between 40° and 50° south latitude, and 30° west of the meridian of Greenwich. They are of a light brown colour; dwell in small villages; and live entirely by commerce, which they cultivate with the greatest skill and industry. Their dress is very simple: their habit is a cloth, and a strip of cloth round the waist. Their arms are the bow and arrow, and the machete. Their religion is very simple: they have no images; and their priests are called Jackals, and are not allowed to eat meat. They have been described by several travellers, as the most industrious, the most religious, and the most virtuous race of people in the world.
Mull of Cantyre. The project of forming this canal was first started about sixty years back, with the co-operation of the then Lord Provost, Sir John Bennie having surveyed the ground and reported favourably, an Act of Parliament was obtained, a company was formed in 1798, and the works were forthwith commenced. The canal was opened in 1801. The canal, although not more than 9 miles in length, has been of outstanding importance in the west of Scotland and the Highlands; the original shareholders of the canal company, however, have never received any return for the outlay of their capital. The number of locks in the canal is 11, the average breadth is 24 feet, and the depth of water 10 feet; 12 necessary 125 feet deep, in which no water could be maintained. Since 1816 the canal has been under the management of the Commissioners of the Caledonian Canal, with the navigation of which it is intimately connected; and these canal improvements formed important part of the inland passage between Glasgow and Inverness. Vessels of 200 tons burden can pass through the Crinan Canal.

CROKER, RIGHT HONOURABLE JOHN WILSON, was the representative of a branch of an ancient family which was settled for many generations at Linhean, in South Devon. A member of this family emigrated to Ireland about the year 1600, and his sons distinguished themselves at the capture of Waterford in 1650. Various descendants of this branch of the family, who have been prominent in Ireland, of whom, were increased from time to time by marriages with influential families. Mr. Croker, the father of the subject of our present memoir, was, for many years surveyor-general of Ireland, and he began his career by entering into an apprenticeship to a merchant. He married with Hester, daughter of the Rev. R. Rathborne, he had an only son, John Wilson Croker, who was born in Galway, December 20, 1790.

After receiving his early education at a school in Cork, where he displayed great precocity and an inquisitive disposition, he was entered at Trinity College, Dublin, at the age of sixteen, under the late Dr. Loyd. He soon began to show extraordinary readiness and ability by the part which he took in the 'Historical Debating Society,' since superseded by the 'University Debating Society.' He began also to put out and developing the characters of young men, and preparing them for their appearance afterwards on the stage of public life. So highly did the society esteem the share taken in its proceedings by Mr. Croker, that it voted him its first gold medal. Intended by his parents for the study of the law, Mr. Croker had no sooner taken his B.A. degree in 1800, than he was entered as a student at Lincoln's Inn; but he continued to reside in Dublin, and to mix with the society of that city. He had obtained a situation as a shorthand writer, and he had leisure hours on his hands, and these he devoted to literature. His first production as an author, if we except a short paper of mere ephemeral interest, was a series of 'Familiar Epistles to J. F. Jones, Esq., on the Present State of the State of Ireland,' 1806, compiled from much information, as followed in 1806 by his 'Intercepted Letter from China,' both anonymous. Both were clever and caustic satires, excited much curiosity and attention, and ran speedily through several editions.

In 1807 he published a work of a graver kind on 'The State of Ireland, Past and Present,' in evident imitation of the treatise of Tacitus, 'De Moribus Germanorum.' In this pamphlet he strongly advocated Catholic emancipation. At the close of the preceding year Mr. Croker was employed as counsel for Sir Josias Bowley, at the election for Downpatrick. Sir Josias withdrew just before the election, and Mr. Croker was nominated in his place, but was defeated by a small majority. In the following May however he returned for Downpatrick, on an impeachment petition.

He had not been long in parliament when an opportunity offered for the display of his oratorial powers. Early in 1809 the Duke of York was brought practically upon his trial in the House of Lords, consisting of the Hereditary Guards, and the most and best successful speech made in defence of his Royal Highness against Colonel Wardle's motion of censure, was delivered by Mr. Croker on the 14th of March. This speech contained a minute dissection of the evidence for the right forward against the duke, and was couched in vigorous and pointed language. It may be presumed that the grateful sense which his Royal Highness thenceforth entertained for this support hastened the advance of Mr. Croker to office. In the course of the same season the late Duke of Wellington, then Sir Arthur Wellesley, and chief secretary for Ireland, being obliged to repair to Dublin, entrusted to Mr. Croker the parliamentary business connected with that country. He fulfilled the trust with much ability and discretion, that shortly afterwards Mr. Pelham, when he formed his ministry in 1809, offered to Mr. Croker the post of Secretary to the Admiralty. For upwards of twenty years Mr. Croker continued to discharge the duties of this office with great success, and by the appointment of First Lords of that department, and under King William IV. when Lord High Admiral. During this time he sat in parliament for various boroughs; amongst others for Aldborough, Yarmouth, and Bodmin; and in 1827 he had the satisfaction of winning the election to the Admiralty Board by the nomination of Lord Plunket to the chancellorship and peerage, with whom he had twice unsuccessfully contested the seat; but his views being in favour of Catholic emancipation, Mr. Croker was again defeated. He took a very prominent part in the parliamentary committee appointed to consider the question of erecting New London Bridge; and his zeal for science and literature was shown in another way soon afterwards, by founding the Athenæum Club. He was amongst the earliest advocates of the state encouragement of the fine arts. His speech on the proposed purchase of the Elgin marbles was much in advance of the general tone of parliament on such subjects. When the Reform Bill was proposed, Mr. Croker opposed it at every stage by powerful speeches and a ready pen, as he considered it a revolutionary measure.

The passing of the Reform Bill compelled Mr. Croker to withdraw from parliamentary life. Even during the most active portion of his legislative career he had been much unemployed. His printed speeches and pamphlets on current political questions amounted to a very considerable number, and his contributions to the 'Quarterly Review,' extending over more than a quarter of a century, would alone fill several volumes. His most extended work, however, was in the field of 'History.' His 'History of England,' in 4 vols., 8vo, published in 1821, which was handled with considerable severity by Mr. Macaulay in the 'Edinburgh Review.' His poems of 'Ulm and Trafalgar,' and 'Talavera,' are the best known and most admired of his productions. 'A History of the Decline and Fall of the Roman Empire' is a highly popular book for children. The following is a list of the most important works not mentioned above, which were either published or edited by Mr. Croker: 'A reply to the Letters of Malachi Macarogruhel,' 'Military Events of the French Revolution of 1830,' 'Letters on the Naval War with America,' and 'Songs of Trafalgar.' He was also the author of several lyrical poems of merit, including some touching lines on the death of Mr. Canning, which occasioned his own death in 1819. He had also edited the 'Suffolk Papers,' 'Lady Hervey's Letters,' 'Lord Hervey's Memoirs of the Reign of George II,' and 'Walpole's Letters to Lord Hertford.' He died August 10, 1857.

CROKER, THOMAS CROFTON, was born January 15, 1762, in the city of Cork, son of General James Crofton, Major of Major Thomas Croker, of the 38th regiment of foot. At the age of fifteen he became an apprentice in a mercantile establishment in Cork. Between the years 1812 and 1816 he made excursions occasionally on foot in the south of Ireland; and it was during these rambles that he commenced making his collections of the legends and songs of the peasantry in Ireland. In the year 1816, Moore, in an advertisement to the 7th number of the 'Irish Melodies,' expressed his obligations to him for about forty Irish airs which he had sent, for many curious fragments of Irish poetry, and for several interesting local traditions. Crofton Croker had also acquired considerable skill in making pen-and-ink sketches, and some of them were exhibited at Cork in 1818.

Major Croker died in 1818, his widow soon afterwards made application to Mr. John Wilson Croker, then secretary to the Admiralty, who was a friend of the family, but no relation; and through his interest in February, 1819, Thomas Crofton Croker was admitted to the inner bar, receiving the salary of 24l. a week. While in this situation he contributed to the introduction of lithography into the Admiralty 'as a substitute for transcribing several copies of the same document, and for confidential columns; and he had for many years been a member of the secret committee of the Admiralty. He subsequently became a clerk of the first class, with a salary of 800l.; and he retired in 1850 with a pension of 880l.

Mr. Crofton Croker's first literary work was his 'Researches in the South of Ireland,' published in 1824, in 4to, and con-
sisting for the most part of the notes made during his early
excursions in 1812-1815, and during a sojourn of four
years in his native city. His works include the "Fairy
Legends and Traditions of the South of Ireland," London,
1828, 3 vols. Sm. 8vo. In the first edition of this work he
was assisted by Dr. Maginn, Mr. Pigott, and Mr. Keightley; but the materials supplied by
his associates, or at least most of them, were afterwards
omitted. A second edition was illustrated with etchings,
after sketches by Maclise, then, as Croker states, "a young
Irish artist of considerable promise." The "Fairy Legends"
appeared in 1834 in one volume, forming a part of the
"Fellows' Magazine," which was eventually a very
successful monthly journal. In 1833, the year in which he
produced a long complimentary letter from Sir Walter Scott;
and on the 30th of October 1836, he was introduced to
Sir Walter at the residence of Mr. Lockhart in Pall Mail. His
personal appearance is thus described in Scott's Diary —
"A small, thin man, not at all what I should have
expected, a very easy and winning manner, and a strong
possessing manner, something like Tom Moore."

In 1835 Mr. Croton Croker published "Legends of the
Lakes, or Sayings and Doings at Killarney, collected chiefly
from the manuscripts of Rev. D. Adolphus Lynch, Esq., R.P.
King's German Legion," London, 2 vols. Cr. 8vo. This work
was followed in 1838 by two small novels — The Adventures
of Barney Mahoney, and My Village versus Our Village,
of which the first was very favourably received, but the second
was omitted. He published a volume of "The Popular Songs
of Ireland," 1830. He was a contributor to some of the
annuals which were in fashion about 1830-40, especially to
The Amulet, and Friend's Offering; and he edited for two or three years The Christian
Magazine, a monthly journal of much importance, for
antiquties, and he was early elected a Fellow of the Society
of Antiquaries. He was chosen a member of the Royal
Irish Academy in 1827. He took part in the foundation
of the Camden Society in 1839, and of the Percy
Society of Cumberland, and was a member of these societies, and he edited some of the works published
by them. When the British Archaeological Society was
founded in 1843, he became one of the Committee. He was
also a member of the United Service Institution, of the Irish
Archaeological Society, of the Numismatic Society, of
the Hakluyt Society, and he was perpetual president of the club
of antiquaries called the Society of Noviuganians. He had
collected an extremely interesting museum of Irish anti-
quities, and he offered the collection to the nation, but
he died at his residence, Old Brompton, London, August 8, 1864.

CROMBIE [DUNDEE]

CROMBIE [DUNDEE]

CROSIE, ANDREW, a celebrated experimenter on
electricity, was born in 1770. He was a solicitor in Court, in the parish of Lochgilp in Argyllshire, on the Quackton Hills in Somersetshire, on June 17, 1774. His father was the proprietor of the estate, to which he succeeded in 1800. He was educated at the school of the Rev. M. Sayer, at Barmouth; and he had for school-fellows W. J. Broderip, the Rev. John Ewing, and other equally celebrated men. In 1802 he matriculated at Brasenose College, Oxford, where he was very uncomfortable, the habits, especially that of drinking, being particularly unsuited to him. He returned home in June 1803, on account of the illness of his mother, who shortly afterwards died. Even when at school he had
become greatly attached to the study of electricity, and on
settling on his paternal estate he devoted still more of his
attention to the subject. He provided himself with electrical apparatus, and pursued his experiments wholly independant of
theories, and searching only for facts. In a cavern near
his residence, called Holweil Cavern, he observed the sides
and roof covered with aragonite crystallisations, and his observations enabled him to conclude that the crystallisations
were the "effects, at least, we may say, of electricity." This
induced him to make the attempt to form artificial
crystals by the same means, which he began in 1807. He
took some of the water from the cave, filled a tumbler, and
exposed it for some days to some Bosch's acid, and, alone, letting the platinum wires of the battery fall on opposite
sides of the tumbler from the opposite poles of the
battery. After ten days of constant action he procured crystals
of carbonate of lime, and subsequently by altering the arrange-
ments he produced them in six days. He found however
that darkness was essential to the certainty and rapidity of
their production. He carried an insulated wire above the
poles of the battery, and divided the water into two parts, one
quarter, afterwards shortened to a distance of 1,800 feet.
By this wire, which was brought into connection with his
apparatus in a chamber, he was enabled to see continually
the changes in the state of the atmosphere, and could use the
fluid so collected as a dry battery. In 1816, at a meeting of country gentlemen, he propagated "that, by
means of electrical agency, we shall be able to communicate
our thoughts instantaneously with the uttermost ends of the
earth." But though he foresees the powers of the medium,
it did not occur to him to apply it in connection with the
propagation of electromagnetism, in the form in which they are produced by nature, including one, sub-niteplate of copper, an entirely new mineral neither found in nature nor
formed by art previously. His belief was, that even diamonds
might be formed in this way. Still he worked alone; he
published none of his experiments to the world, and he pro-
ounced no theories. At length, in 1836, the British
Association for the Advancement of Science held its meeting
in Bristol, and Mr. Crosse attended it, intending to be an adderly
only to the meeting. While there, he met some scientific gentlemen there, he was induced to explain them
publicly, and though unprovided with apparatus, they were
so struck with the importance of the facts, that he was publicly
complimented by the president, the Rev. Mr. H. Crosse, and
other members, as the second greatest experimenter, after Professor Sedgeick, and others. A few months after this meeting, while pursuing his
experiments for forming crystals from a highly caustic solution
out of contact with atmospheric air, he was greatly sur-
prised, as he states, to find that his crystals had a highly red
and reduced to powder, was mixed with carbonate of
potash and exposed to strong heat for fifteen minutes.
The mixture was poured into a black-lead crucible in an air
furnace. It was reduced to powder while warm, mixed with
boiled water, and brought to a boil. The council of the Royal
Society at that time was under the presidency of the Rev. Mr.
Weeks, of Sandwich, afterwards produced them in fer-
rocyanurall of potassium. This discovery occasioned great
excitement at the time. The possibility was denied, thought
then, if this was the case, it was as great a discovery as those
similar appearances in his own electrical experiments; and
he was accused of impiety, as aiming at creation. He
was much hurt by these attacks, for he was a truly pious man.
He says he was inclined to believe that the insects were
produced by a certain kind of fermentation, similar to that
which caused the vinegar to ferment; and adds, "I have formed no visionary theory that I would travel out
of my way to support." He attempted to give no explanation of what he admitted he could not comprehend,
and in answer to a personal question, who had written to him, calling
him " a reviver of our holy religion," he replied that he was
sorry if the faith of his neighbours depended on the claw of
a mite. These insects, if removed from their birthplace, live
and propagate, but uniformly die on the first recurrence of
heat, and are entirely destroyed if they fall back into the
fluid whence they arose. This was the most remarkable
of his discoveries; but his labours were in some instances more
useful. He invented a method, which was patented by
others, for purifying sea-water by electricity, which water
was subsequently made use of in some cases. He was also
capable of being used for the improvement of wines, by
removing the predominance of bitartrate of potash; to the
improvement of spirits by removing acidity; and to the
stopping of the fermentation of cider. He also made expe-
rimented on the use of electricity in the vegetable kingdom; he
noted that positive electricity advanced the growth, as was
shown by the cultivation of two vines by Mr. Boys of Margate; and
that negative electricity favoured the growth of fungi, and
induced them to grow like the rot in the potato. Mr. Andrew
Crosse did not confine his labours to the vegetable and
mineral worlds. Though living chiefly on his estate in the country, he took
an earnest part in all local affairs. He was an active magis-
trate, just, but benevolent; he advocated the instruction of
the poor, and he gave lectures on various subjects to the
neighbouring institutes; he left a quantity of poetry, con-
siderably above mediocrity, which he could not be induced to publish in his lifetime, but which has been given to the world by his widow, in a memoir of him written with much good taste; and he died, after a short illness, July 6, 1836, leaving behind him the character of a pious good man, and an indefatigable searcher for truth.

CROCHET, WILLIAM, Doctor of Music, was born in 1770, in the city of Norwich. While yet a child, he exhibited facility in music, and was at once perceived to be a boy of quite marvellous, and rival those of Mozart. An account of his precocious talents was given by Dr. Burney, author of the 'History of Music,' and is printed in the 'Philosophical Transactions' for 1778, when the infant prodigy was only four years old. He was educated at the University of London, and was appointed Professor of Music in the University of Oxford, and the university also conferred on him the degree of Doctor of Music. In 1824 he was appointed Principal of the Royal Academy of Music. He performed in public for the last time in 1834 in Westminster Abbey, during the royal festival, when he presided at the organ on the third day. Dr. Crochet composed a very large number of works, as organist of St. Paul's and composer of the 'Palestrina,' and some pleasing vocal pieces, among which may be mentioned the 'five odes for five voices, 'Mona on Snowdon calls.' He also published 'Elements of Musical Composition and Thorough-Bass,' 1816, and 'Specimens of various styles of Musical Allegro and Variations.'

Dr. Crochet, during the latter years of his life, resided at Banbridge, Antrim, with his son, the Rev. W. R. Crochet, master of the free grammar-school. He died December 29, 1846, and was buried in his parish church, where the mourners were numerous.

CROZIER, CAPTAIN FRANCIS RAWDON MOIRA, second in command of the ill-fated Franklin expedition, was born at Banbridge, county Down, Ireland. He entered the navy in June 1810, and, under the command of Sir Thomas Stewart, sailed from England on the 24th of July for Pico's Island, which was found peopled by the descendants of the mutineers of the Bounty. In 1824 he was appointed master-of-the-ferry, and he accompanied Fawcett in three of his voyages to the Polar Sea. In 1829 Mr. Crozier was made lieutenant, and was employed on the coasts of Spain and Portugal till December 1836, when he sailed with Captain (now Sir) James Ross, to search for the missing whalers in Baffin's Bay. His reputation for perseverance, which he had gained in the exploration of Antarctica, was secured by the death of his principal and the promotion of the Terror in the expedition under Sir J. Ross for the exploration of the antarctic regions, which sailed in 1839, and was absent three years. In March 1845 he was re-commissioned to the Terror, and sailed with Franklin to discover the North-West Passage ; since which time he has not been heard of. He was in the prime of life on his departure, and died probably in his fifty-third year. He was a Fellow of the Royal and Astronomical Societies; a man of great merit, was distinguished by great devotion to duty as for love of science.

CRUDEN, ALEXANDER, the author of the well-known Concordance, was born at Aberdeen in 1701. He studied at Marischal College, but whilst there, his conduct was marked by an idea of doing what was wrong and he was turned out of the university four years later, and, as it was found necessary to abandon his intention of becoming a minister of the Church, he came to London in April 1724, and subsisted by giving lessons in Greek and Latin. Afterwards he obtained a situation as tutor, and in that capacity resided for some time in the Isle of Man. In 1729 he opened a bookseller's shop under the Royal Exchange, and occupied his leisure hours in the preparation of his 'Concordance of the Old and New Testament,' which appeared in 1737. It was dedicated to Queen Caroline, and Cruden had calculated sanguinely on her majesty's favour. The queen died however just after the publication of his book, and the disappointment brought out the fact that it was rankly plagiarised from the well-known 'Concordance to the New Testament' of a Mr. Asbury at Basinghall-street, where he was confined from March 23 to May 21, 1738, when he escaped. He persisted in asserting that he was of sound mind, and brought an action against the keeper of the asylum and others; but as might be supposed he was not directed by the judge to find a verdict for the defendant.

Crudens published an appeal to the public, under the title of 'Mr. Crudesley greatly Injured on account of a Trial between Mr. Alexander Crudens, bookseller, and an account, plaintiff, and Mr. Congre, Matthew Wright, John Oswald, and John Davis, defendants, in the Court of Common Pleas, in Westminster Hall, July 17, 1738, on an action of Trespass, Assault, and Impeachment... with an account of several other Persons, who have been unjustly confined in Private Madhouses.' The whole tending to show the most necessary there is for the Legislature to regulate Private Madhouses in a more effectual manner than at present, 5vo, 1739.Crudens, who appears to have been treated while in the asylum, by the furious reader of printers' proofsheets, and in the occasional preparation of indexes. Among others he is said to have compiled the elaborate index to Newton's 'Milton.'

He now entered on that part of a strange kind of autobiography, under the title of 'Adventures of Alexander the Corrector.' A second time it was deemed necessary to place him under temporary restraint at Chelsea; and again he brought an action in the Court of King's Bench for an injunction. He took part in the proceedings against the parties who had him confined, with as little success as before. On obtaining his liberty he became again a bookseller, and returned to his ordinary occupations. Subsequently he published the second part of his Adventures, in which he gave the history of his second confinement, or 'Chelsea Campaign,' of which he says, in his preface, 'itLad been a part of his work, as an honest and moderate man, to bring the public into possession of the results of his experience, in which he had lived; to give to the world the story of his own life, and thus to persuade others not to proceed on the same line of action.'

Three editions of it were published during the lifetime of the author. It continued to print for many years, and it has since gone through innumerable editions of all degrees of correctness: one of the most esteemed is that of 1810.

CUBITT, THOMAS, was born in 1788, and was the son of a labouring man at Buxton, a village in Norfolk. Thrown
CUC 164 CUM

easily on his own resources, and denied the advantages of what is called a liberal education, he nevertheless rose into eminence by skill and industry combined with integrity, and amassed a fortune by the judicious management of his estates. He died in 1645, and his son, Robert, continued the work of his father. He was a man of great energy and achievement, and is said to have spent large sums in the establishment of new industries and the improvement of existing ones.

Coniston. Coniston is a small market town and parish in the county of Cumbria, England. It is situated at the head of Lake Windermere, and is noted for its beauty and its many lakes and mountains. The town has a population of about 5,000, and is surrounded by rich agricultural land.

Cumbrian Rocks. The Cumbrian Rocks are a group of rocks that occur in the north of England, in the counties of Cumbria and Lancashire. They are composed of various types of sedimentary rocks, including sandstone, shale, and limestone, and are mainly of Carboniferous age. The rocks are important for their fossil content, particularly for the Silurian and Devonian periods.

CUMMINS. Alexander Cummins was a British geologist and paleontologist who worked in the late 19th and early 20th centuries. He is known for his work on the geology of the Scottish Highlands, and for his contributions to the study of the Silurian System. His most important work was on the Cumbernauld Limestone, which he described in detail in his 1900 monograph, "The Silurian System of Cumbernauld."
certainly is merely as to the name by which certain portions of them shall be called.

CUMMINGTONITE, S. 2.

CUMMINGTONITE, an American mineral belonging to the hornblende series. It is fibrous, of an ash-grey colour, with a slight silky lustre. It is found at Cummington and Plainfield, in Massachusetts. (Dana, Mineralogy.)

CUMNITA, a genus of plants belonging to the natural order Labiatae.

It has a 13-celled calyx, ovate, tubular, equal, 5-toothed, the throat villous inside. The corolla having the tube equaling the calyx, naked inside, and the limb bluish or white, in five-series, is nearly tube-shaped; lower lip spreading, trid, with nearly equal entire lobes, the middle lobe rather the largest and emarginate. The stamens 2, erect, excluded, without any rudiments of the upper two; filaments glabrous, toothless; anthers 2-celled, cells parallel, or at length divergent.

A. styloides, native of Carolina, on dry mountains, is a branched herb with short glabrous branches, but pubescent at the nodes. The corolla is about twice as long as the calyx, and is pubescent inside, and of a red colour. It is employed medicinally, where it grows, in slight colds and fever. Its epidermis and anthocyanin pigment are both valuable.

C. microsphala is also used medicinally in coughs and colds, in Brazil, where it grows. It has a procumbent stem, with scarcely pubescent branches; the leaves peltate, oblong, or obovate, obtuse, quite entire, or subsparsely serrate, with a short acuminate point, and flab. The corolla is white; the throat villous inside.

There are several species of this genus, none of which are of any known use except those above mentioned.

CUPANGUS. (Parisitaceae.)

CUPULE, a kind of cup or involucry surrounding certain kinds of fruit, and composed of bracts more or less grown together. In the oak the cup of the acorn is the cupule; in the hazel-nut it is the husk; in the beech and chestnut the prick, in the filbert the covering, and in the lobed bract.

CURASSOW. (Cracidae.)

CURRAN, JOHN PHILPOT, was born on July 24, 1760, at Newmarket, in the county of Cork, Ireland. His parents were respectable, but not wealthy; his father having been an officer to a municipal court, and possessing the advantages of a classical education. His mother, perceiving early indications of talent, was in hopes of his becoming a clergyman, and efforts were accordingly made to procure him a suitable education. He was first procured some instruction from the Rev. Nathaniel Boyce, the resident clergyman, with whom he maintained a continued friendship. He was next sent to the Free Grammar-School at Middleton, and afterwards entered as a sirar in Trinity College, Dublin. After the utmost love and attention to learning, and entering at that university, he abandoned his first intention of entering the church, and determined to adopt the profession of the law. Accordingly, having passed through the university with great credit, he went to London, and entered himself at the Middle Temple in 1773. Here he straitened means occasioned him some inconveniences, but he studied law with considerable assiduity, and practised oratory at some debating societies, where he is said to have displayed his talent for energetic and socratic speaking. In one of the vacations, between the terms, he returned to Ireland, and married a daughter of Dr. Creagh in 1774. With her he received a small portion, which somewhat smoothed the remainder of his term of probation, and, in 1776, he was called to the Irish bar. His success was almost immediate. His style was precisely suited to the Irish courts: humourous, discursive, often flowery and poetical, vehemently appealing to the feelings, never wearying by dry legal arguments, but which, by their vehemence, dryness by occasion, and wit or satirical illustrations, and he soon obtained a leading business. His social habits also operated in his favour, and though he had already adopted a political belief in opposition to the reigning government, he was a general favourite everywhere, and was not attacked by any bearing to the judges won him the favour of the public. The fearlessness of his addresses however sometimes brought its inconveniences. As counsel in an action for assault by the Marquise of Donegall on a poor old Roman Catholic clergyman, he had styled Mr. St. Leger, one of the witnesses for the defence, “a renegade soldier, a drummed-out dragon;” a duel followed, when he declined returning Mr. St. Leger’s fire, and the affair ended. He had been always a warm political man, and it is said that he was always present as member for Kilbeggan, on the interest of Mr. Longfield. As a spec- men of the state of the Irish parliament, we may mention that soon after entering the House of Commons he found himself differing in political opinions with his patron, and as he had no way of procuring the return of his seat, he was offered another seat, to be filled by any one Mr. Longfield might choose to appoint. That gentleman declined the offer; but in the succeeding parliament Mr. Curran bought a seat for himself. In 1772 he was appointed assessor to the court of taxes, and generally acting with Mr. Grattan and the few liberal members who then had seats. His speeches were of a very similar character to those he made at the bar, and he was often appointed to make the reply from his readiness and happy facility in retorting charges or damaging the positions of his opponents. He supported the formation of the Irish Volunteers in 1778, and the unconditional appoin- ment of the Prince of Wales to the regency on the occasion of the king’s illness in 1779, and took a seat on the government led to a duel, first with Mr. Fitzgibbon, afterwards Earl of Clare, and then with Major Hobart, in which Mr. Curran was the challenger, in both of which neither party was injured. It was in 1774 and the few subsequent years that Mr. Curran’s name was foremost in the Irish question, and as his fame spread to the United States, he was appointed a volunteer to the Irish House of Commons before the introduction of the meas- ure for the Union, of which he strongly disapproved, and which he ever continued to lament. The assassination of 1803 brought trouble into his family; Robert Emmet, one of his leaders had formed an attack on Miss Curran, which was returned; and his correspondence with her, with his visits, sometimes secretly, to her father’s house, led to a suspicion of Mr. Curran’s loyalty, and to the searching of his house, and conviction of himself, for Mr. Curran, Mr. Grattan, and others, had been continually pointing out to the government that their measures were driving the people towards rebellion. The warnings were unheeded, and in 1784 Mr. Hamilton Rowan was indicted himself, and the two brothers, Sheares, Theobold Wolfe Tone, and Matthew Curran. He had retired to the Irish House of Commons, and the Irish House of Commons was abolished by the act of 1800, which afterwards took this name, of which he was secretary. Mr. Curran was his counsel, and made an eloquent and vigorous defence, but Mr. Rowan was convicted and sentenced to transportation, and after the breaking out of the rebellion in 1798 he was the counsel generally employed by the accused, among whom the most remarkable were the two brothers Sheares, Theobold Wolfe Tone, and Matthew Curran. He had retired to the Irish House of Commons before the introduction of the mea- sure for the Union, of which he strongly disapproved, and which he ever continued to lament. Mr. Emmet had named him one of his counsel, but he did not act. Mr. Emmet was convicted and executed; his fate and his sufferings has been the subject of ‘Two Men of Moreau’s Irish Melodies.’ Upon the death of Mr. Pitt, in 1806, the Whig ministry under Lord Grenville created Curran Master of the Rolls in Ireland. This appointment did not give him satis- faction; it withdrew him from politics, and as his mind was not judicial, he felt himself out of place: he thought he had been neglected, and his health declined. He held the office till the early part of 1813, when he resigned; and he died in London on October 14, 1817. Mr. Curran in the course of his life wrote a considerable number of verses above ordinary merit, but which bears no comparison with his eloquent speeches.

CURSITOR BARON. This office, or rather sinecure, was abolished by the statute 19 & 20 Vict. c. 86, which also makes provision for the performance of its almost nominal duties.

CUSHAT (Colymbus diophius). (COLUMBIDÆ.)

CYAMELIIDE. [CHEMISTRY, s. 3.]

CYANOGEN, CHLORIDE OF. [CHEMISTRY, s. 1.]

CYANUS, a genus of plants belonging to the family Camellietoidea.

CYCLADIZO, a family of Lamellibranchiato mollusks. It is a group of fresh-water mollusks, whose shells resemble those of Kuliia or of Astarea, but whose soft parts present structures conspicuously distinguishing them from the tribes to which those shells belong. The shells are more or less tumid, equilateral or inequi- lateral, thin, as in our British forms, or thick, as in the foreign Cyrena; smooth or concentrically striated and furrowed, and covered with an epidermis, The hinge is furnished with cardinal and lateral teeth, and the ligament is external.
The animals have plain-edged mantles open in front, siphonal tubes produced, and either partially separated or completely united to their unfringed extremities, and a large linguiform foot. They live buried in the mud of slow streams, lakes, ponds, ditches, and springs. Our native species are all ovo-viviparous. They breed readily in confinement, and often exhibit considerable activity, ascending the sides of the vessel in which they are placed. (Forbes and Hanley.) This family contains two British genera, Cyclos and Punticium. Cyclos has the shell equivalent, thin, sub-ovoidal, smooth or concentrically striated; the large, oblong, inhabits the oblong, centrically united tabes of the area, and the oblique, a prominent, usually inflated, and slightly insular. C. ricosta has the shell oval, globose, striated; umbones obtuse; dorsal area with a small lunular impression; ligament manifest.

The ordinary length of the finer specimens is 104 lines, and its breadth about two-thirds of an inch.

The tubes of the animal are tinged with rose or tawny, and when fully protruded are nearly equal, the branchial, if either, being longest.

The foot is large, white, and ligniform; the mantle white; the labial palps long, triangular, and strongly striated. It is sinuous in its habits.

Forbes and Hanley give the following localities:—The most prominent is the river Thames; it is found likewise in the New River (Raij); the Treat (Jenyns); the Lea (S. H.); the canals about Leamington, in Warwickshire (Thompson); streams in Yorkshire (Baird). In a pond at Enville, Staffordshire, a young specimen (Jeffrey). It has not been taken either in the Thames, or the Dee, or the Severn, or the Thames, or the Dee, or the Severn, or the Thames, or the Dee, or the Severn, or the Thames, or the Dee, or the Severn.

In Germany, France, and Belgium; and as a fossil is found in the Pleistocene Fresh-Water Beds of the south of England.

C. corvis, Linn. Shell sub-ovoidal, almost smooth; umbones obtuse; ligament inconspicuous. There is a sub-ovoid variety (apparently the Stagmosa of Mr. Heppard), which is flattened towards the ventral margin, and has the pedicellum and swollen umbones peculiarly prominent. The dimensions of the larger typical form are six lines and a quarter in length, and five lines in breadth; of the variety five lines and a half in length, and four and three-quarters in breadth.

The animal is white, its sub-elongated siphonal tubes tinted with pale flesh-colour. Mr. Jenyns observes that the superior tube is sub-ovoidal, with a small aperture, the inferior cylindrical and truncate, with a wider aperture.

This very common species is a general inhabitant of rivers, ponds, and ditches throughout the country. It appears to thrive equally well both in running and in stagnant water. (Jeffrey.)

It is also generally distributed throughout Europe, and occurs fossil in fresh-water strata of the pleistocene age in the valley of the Thames.

C. cictolenta has the shell more or less rhomboidal; umbones narrow, more or less prominent, capped.

This species is apparently less frequent in the north than in the more southern parts of England. Mr. Alder has found it near Newcastle; Mr. Bean at Scarborough (where it is not scarce); Mr. Thompson at Lichfield; and Captain Brown records the vicinity of Manchester and the lakes of Westmorland for its localities. Montagu met with it in Devonshire and Wiltshire; Mr. Jenyns at Bookham Common in Surrey; and more sparingly in Cambridgeshire; and Mr. H. Strickland at Hornea in Yorkshire. Mr. Jeffreys has taken it in the Clumber Lake, Nottinghamshire, and in the neighborhood of Bristol. In Ireland it is also rare. "On the Continent it occurs in Sweden, Germany, Belgium, Holland, and Italy. The C. portentosa of Sax, in depth of the ventricosity of the adult, is very closely allied, especially in outline, to this species, and may be regarded as its transatlantic representative." (Forbes and Hanley.)

Punticium has the shell equivalent, thin, usually sub-ovoidal, inequilaterial, smooth or concentrically striated; bings with one tooth in the right and usually two in the left valve; also lateral teeth; ligament external, inserted at the shorter side.

The species are very small bivalves, living in similar localities with Cyclos, and not uncommon even in ditches through meadows.

P. punticium. Shell rounded, oval, not greatly inequilateral; valves not slightly striated; valves not swollen, always a little compressed below; umbones usually broad, and but little projecting. This is by far the commonest of the small Punticium in this country. It is found abundantly in ponds and ditches. It inhabits generally northern and central England.

P. pulchellum. Shell small, striated (not grooved); umbones simple and without appendages. There are many varieties of this shell. It has a great tendency to assume a multiplicity of forms. The average size is a line and a half long, and a line and a quarter broad. It is very common in many parts of Great Britain.

The other British species of this genus are P. Hericole,
P. ricota, P. punctatum, and P. decusatum.

C. CYTHERIES. *C. Cristata*, a small, elongated order of Exogenous Plants. The order consists of shrubs with evergreen simples leaves without stipules. The flowers usually in racemes. The calyx 4-5- parted. It has 5 distinct petals, with an imbricated modification. The ovary is 3-4-celled, always chorisomatous. It is composed of some number of carpels different from that of the calyx, corolla, and stamens; solitary pendulous ovules, a short style, the stigma with as many lobes as there are cells of the ovary. The fruit is a succulent capsule or a drupe; the seeds inverted; the leafy in the axis of a very large angular, or rounded, or in some cases, with a very long stalk. This order is related to Olacaceae and Pitsocarpaceae. All the species are inhabitants of North America. Nothing has been recorded of any ease to which they are applied.

C. CYTHERES, a genus of entomostracous crustaceans, belonging to the legation Leptopodops, the order Ostroiscidae, and the family Cythrididae. The species are few very commonly in Great Britain. [Branchiopoda.] Mr. Rupert Jones, in his "Monograph of the Entomostraca of the Cretaceous Formation of England," describes the five fossil species belonging to this genus. [Entomostraca.] The same author describes ten species of this genus as fossil in the Permian Rocks of England.

C. CYTHERES is a genus separated from the group of species known as C. cytheres by Mr. J. Jones. It has the following characters:—The animal is unknown. Carapace-valves or shell of an almost regular oblong shape, the dorsal and ventral margins lying nearly parallel to each other. Surface of a very irregular appearance, being wrinkled, ridged, and beset with tubercles, or excavated or strongly toothed on the margins.

Dr. Baird has described three recent species, whilst two fossil forms have been described by Mr. Jones from the chalk. *Bairditia* is a group of species formerly referred to Cytheres, and separated by M'Coy. The valves externally are convex and smooth, sometimes flat, pitted or spined, never ribbed or granulated; the hinge is simple.

This genus has no recent species. Six species have been found in the chalk.

C. CYTHERES is a genus separated by Jones from Cytheres. It embraces species of Cytherina of other authors. The carapace valves are oblong, and vary in the convexity and smoothness of the surface; the right valve is larger than the left, and its contact margin thicker than that of the opposite valve. Six fossil species have been described from the chalk.

DAGRIDIUM, a genus of Gymnocalyciaceous Plants belonging to the natural order Tertiary. One of the species, D. far- 
folium, the Kakaterra-Tree of New Zealand, acquires a 
height of 200 feet. From its branches may be manufactured a 
beverage resembling in antiseptic qualities the well-
known spruce-beer.

DAGUERRE, S. JACQUES MANDE, was born in 1780 at Cormeilles in the department of Seine-et-Oise, France. 

At the outset of his life he obtained a situation in a government 
office, but he early quitted that employment, and became a 
peep of M. Dagoty, scene-painter at the opera. As a scene-
painter, Daguerre in a few years surpassed his instructor, 
and placed himself on a level with the first professors of that 
art in Paris, while he quickly extended the capabilities of the 
art by various ingenious contrivances, which he invented 
for producing increased pictorial effect. He also assisted 
M. Prevost in the preparation of his panoramic views of the 
great cities of the world. The experiment he thus acquired 
suggested to M. Daguerre the idea of producing a scene 
exhibition, in which the illusion should be more 
perfect than in the panoramas, and he invented, in conjunc-
tion with Bouton, a method of so throwing coloured lights 
and shadows upon the view, as to produce the appearance of 
changes of season, day and night, storm and sunshine, etc.

This mode public demonstration of the effects of Daguerre's 
new process, was received with equal success in Paris and 
in a circular structure erected for the purposes in Paris, the 
success was complete. The diorama in fact made what the 
Parisians term a sensation, and no long time elapsed before 
M. Bouton and Daguerre erected a similar building in 
London, to which each picture was removed, when it had 
been exhibited for its season in Paris. For some seventeen 
years pictures followed picture, each rivalling its predecessor, 
but in 1839 a fire destroyed the building, and the view then 
exhibiting in it was destroyed, and the building itself was not 
re-erected, as the public interest in dioramas, which had now 
lost their novelty, was beginning to flag.

M. Daguerre had before this been directing his attention 
to a matter which was destined to secure for him a more 
permanent reputation than his scenery or his dioramas. This 
was the mechanical production of fac-simile delineations 
of objects by the chemical action of light. As early as 
about the middle of the 16th century, Fabricius had dis-
covered the property which salts of silver possess of changing 
colour, and it is said that the father of Daguerre had 
been the subject of many experiments by scientific men. 
Sir Humphry Davy, among recent chemists, has sought by 
various applications of this property to obtain copies of 
simple objects by the action of light; but his was unable to 
prevent them from being effaced when exposed to the 
light. In France M. Niepce began about 1814 to pursue a 
similar course of experiments, and he succeeded in 
rendering the images he obtained insensible to the subse-
quent action of the light; but his discovery remained very 
incomplete when Daguerre commenced similar experiments. 
About 1829 Niepce and Daguerre joined in the prosecution 
of their investigations. Niepce died in 1833, before they 
had made any decided approach to success. But Daguerre 
persuaded, and at length his zeal and rare ingenuity met 
with an ample reward. He discovered in fact a method by 
which he was able so to prepare metallic plates, that by 
placing them in the darkened chamber of a camera-obscura, 
they received a distinct impression of the images thrown 
upon them by the lens of the camera, which he was enabled 
by a subsequent process to render indelible. Some account 
of the steps by which he arrived at this grand discovery, 
the method adopted for producing, rendering visible, and fixing this 
sun-drawn picture, has been recently published in a work 
titled "PRACTICAL PHOTOGRAPHY," S. 1.

It will be enough to say that with re-
markable patience and ingenuity he surmounted every dif-
culty, and eventually produced his discovery, as to its prin-
ciples, perfect. Other experimentalists had in this country and 
elsewhere been at work, unknown to Daguerre, at the same 
time; but to M. Daguerre is due the priority of publication 
of the discovery, and no doubt also the priority of discovery, 
as far as the producing sun-pictures upon metallic plates is 
concerned. What has proved to be the more generally 
applicable process of photography, was as unquestionably the 
result of the independent investigations of our own compa-

DALBERGIA, a genus of Plants belonging to the natural 
order Fabaeae, named in honour of Nicholas Dalberg, a 
Swedish botanist. It has a reputation for yielding a 
papilionaceous corolla, the petals of the keel connected to the 
 apex; 8-10 stamens, sometimes all monadelphous, with the 
tube or sheath cleft in front, sometimes divided into 
equal opposite segments, and in others one side longer 
than the other; a stipitate membraneous complanate kegule, 
the lower orifice of which is called) the flower; 20-30 
seeds, which vary from 1 to 3, are compressed and remote. 
The species are sometimes trees, but usually climbing shrubs, 
with impari-pinnate leaves.

D. aranzé, another of the species, yields a resin very 
similar to Dragon's Blood.

There are about 22 species of this genus, none of which 
are of any known use except those mentioned.

DALKICHT, Edinburghshire, Scotland, a market-town 
and burgh of barony in the parish of Dalkeith, six miles 
S.E. from Edinburgh by road, and eight miles by the 
Edinburgh and Hawick railways. The population of the town 
was 5068 in 1861. The affairs of the haurgh are adminis-
tered by 15 trustees. The town stands on an elevated piece 
of ground, between the rivers North Esk and South Esk, 
and consists of one central thoroughfare, and several small 
streets. The town is clean and generally well built, it is 
lighted with gas, and well supplied with water. Felt and 
beaver hats, straw hats, and woollen stuffs are manufactured, 
and there are corn-mills, a brewery, and a tan-work. The 
market is once a week. It is the capital of Midlothian, 
Scotland. The parish church is an old Gothic building in the 
principal street. Attached to it is an ancient chapel 
containing the recumbent statues of an Earl of Morton and his 
 lady. Adjoining this church is the mortuary chapel of the 
Buchleech family. A splendid new church of an English 
style of architecture, was built in 1840 by the 
Duke of Buccleuch. It is cruciform, and has a steeple 167 
feet high. An elegant episcopal chapel is situated within 
the grounds of Dalkeith palace. The Free Church, United
Presbyterians, and Independents, have places of worship. In the town are two libraries and a savings bank. Dalkeith possesses an extensive park, and a view of the town is an extensive structure, surrounded by a splendid park and grounds. The mansion contains many fine paintings. The North Esk and South Esk unite their waters in the park, a little way beyond the palace, which is situated on an elevated peninsula, formed by the confluence of the two streams. It belonged to the Grahams in the reign of David II. It afterwards passed into the hands of the Earls of Morton, and about two centuries ago was purchased by an ancestor of the Buccleuch family. Charles Edward spent two nights at Dalkeith after the battle of Preston Pans, and the palace has been visited by George IV. and Queen Victoria.

DALRYMPLE, JOHN, was born in the year 1804 at Norwich, where his father was a surgeon in general practice. He was educated for the medical profession under his father in Edinburgh and London. He commenced practice as a surgeon in London in 1827. During the latter part of his career he devoted himself entirely to oculary surgery. He died in 1852. As a surgeon-oculist he was better known for his work on the 'Anatomy of the Human Eye,' which was published in 1854. He was not however known only as a surgeon, but also as a naturalist and accurate microscopic observer. Amongst his papers on these subjects the following are the most important: 'The Structure and Function of the Fish-eye of the Bull-fish' published in the 'Magazine of Natural History,' sect. 2, vol. ii.; 'On the Vascular Arrangement of the Capillary Vessels of the Allantoid and Vitelline Membranes in the Incubated Egg' ('Transactions of the Microscopical Society,' vol. i.); 'On the Invertebrates of the Family Clitellata' ('Annals of Natural History,' vol. v.). In 1849 he read a paper before the Royal Society on a hitherto undescribed infusory animalcule allied to the genus Notornasus of Ehrenberg. This paper was interesting as confirming the discovery of the sexuality of the infusorians, which had been made by Brightwell. This paper was published in the 'Philosophical Transactions,' and in 1850 Mr. Dalrymple was elected a Fellow of the Royal Society.

Mr. Dalrymple was one of the surgeons of the Royal London Hospital. He was a Fellow of the Royal College of Surgeons of England, and in 1851 was elected a member of the council of that body.

DAMAGE. The stat. 1 Geo. IV. c. 87, enabling a landlord to recover damages in the action of ejectment by which he recovers possession, although not repealed, is superseded by provisions to the same effect in the 'Common Law Procedure Act,' 1852.

DAMAN. [DAMAR.] D. MACFADYEN, in Procr. 'On the Natural Order of Plants related to the Farn.' They have all the habit of Dorsiferous Farns, but their spore-cases are ringless and combined in masses, splitting irregularly by a central cleft. The species are all tropical. It embraces the following genera:—

- Kaulliaustus, Anderabellus, Diploloma, Calonectes, etc.

D. ramosa also has a native of the forests of Brazil, and has a twining stem with hairy twigs. The leaves are oblong, remotely and obsolescent, serrated, rough and hairs above, almost or entirely smooth on the under side. The racemes are hairy and hairciliate; the sepals silky. The petals from 1 to 6, somewhat obcordate. The stamens 4, the anther dehiscent, and furnish the valuable called Sambalbusia in East Indies.

D. rubra also has a native of the forests of Brazil, and has a twining stem with hairy twigs. The leaves are oblong, remotely and obsolescent, serrated, rough and hairs above, almost or entirely smooth on the under side. The racemes are hairy and hairciliate; the sepals silky. The petals from 1 to 6, somewhat obcordate. The stamens 4, the anther dehiscent, and furnish the valuable called Sambalbusia in East Indies.
within two days of his death he performed the active duties of his responsible position. He died on the 11th of April 1855.

The distinguishing feature of Sir Henry's mind was its eminently practical character. The establishment of the Geological Survey and the School of Mines was a proof of this. Wherever his knowledge could be made available for practical purposes, his services were at the command of the public. His mind was so broad and his spirit so adapted to the important work of a Towns Commission and also of the Commission of Sewers. He was chairman of one of the juries of the Great Exhibition in 1851. With Sir Charles Barry he formed one of the committee to select building-stone for the New Houses of Parliament. He was entirely successful in having the decision of reporting to the government on the coals suited to the steamery, also with Dr. Playfair and Mr. Smyth in reporting on the gases and explosions in collieries. He was elected a Fellow of the Royal Society in 1819, in 1846 he had conferred on him the honour of knighthood, and in 1848 he was elected a corresponding member of the Academy of Sciences of Paris.

DEBENHAM. (Surprize.)

DEBT. ACTION OF. The peculiarities connected with this action, which led to the use in ordinary cases of the action of assumpsit, have for all practical purposes ceased to exist. Wager of law having been abolished, and the pleadings in personal actions greatly simplified, nothing remains to distinguish the law of mind, and it is only by a specimen so called, from any other action for breach of contract. (Blackst. 2d Comm., Mr. Kerr's ed., vol. viii. p. 162.)

DEDDINGTON. [Oxfordshire.]

DE DICTION. The jurisdiction of the Ecclesiastical Courts, or, as Blackstone says, of a "petty surrogate in the country" to punish "for railing or contumelious words "pro solute anime," by means of the "brutum fulmen of ecclesiastical process," having long been a subject of considerable ridicule, though frequently of grievous opposition to the poor, has at last been abolished by the statute 18 & 19 Vict. c. 41.

DELA ROCHE, PAUL, an eminent French painter, was born at Paris in 1797. Early intending to follow a civil profession, he at first studied landscape, and was in 1817 an unsuccessful candidate for the Academy prize in landscape painting. Convinced that landscape-painting was not his vocation, he entered the atelier of Baron Gros, under whose guidance he made rapid progress in the study of the figure. Gros had himself in a great measure thrown off the classic trammels which his master David had fixed on French art, and Delacroix entirely emancipated himself from their thraldom. But Gros still adhered to the old laws, and many of the conventionalities of art. Choosing this subjects to a great extent from modern history, and painting without much regard to academic attitudes and arrangements, he yet sought to maintain a certain dignity in his work. Delaroche was a forerunner in French art of the modern school of historians and archivists. He was far more learned and architectural in his conceptions, and his study of the great masters was at the same time more profound and less artificial. He was still adhered to the old laws, and many of the conventionalities of art. Choosing his subjects to a great extent from modern history, and painting without much regard to academic attitudes and arrangements, he yet sought to maintain a certain dignity in his work. Delaroche was a forerunner in French art of the modern school of historians and archivists. He was far more learned and architectural in his conceptions, and his study of the great masters was at the same time more profound and less artificial.

DELA ROCHE, M. This eminent painter of landscape, in 1839, was voted a pension by the government, an honour he had long desired. It was a higher order of business, Cromwell contemplating the Corsos of Charles I. He has here imagined a circumstance in itself sufficiently probable, and he has blended it with a calm dignity worthy of the theme. M. Delaroche has been often accused of sacrificing his principal subject to the accessories by his excessive care in the rendering of them, but here the attention is at once arrested by the thoughtful head of the Protector, directed to the life-like face of the soldier, the over-wrappers of the victim and the victor. The sombre color and gloomy shades are entirely in unison with the prevalent impression. Simple as is the idea of the picture, it would perhaps be difficult to name another modern painting which so thoroughly conveys a particular mind of the picture. It is in the collection of the Duke of Sutherland. M. Delaroche also painted some illustrations of Scott's novels. Among the subjects from French history may be named "Une Scene de la St. Barthelemy" (1828); "Le Cardinal de Richelieu" and "Le General Moncey" (1835). Delaroche, being editor of "Le Diable Bleu," found a companion picture to "that of Cromwell contem- plating the Corsos of Charles," and equally well known by the engravings, but certainly far less impressive as a work of art, for the technical skill and vigour of his picture. It is in the collection of the Duke of Sutherland. M. Delaroche also painted some illustrations of Scott's novels. Among the subjects from French history may be named "Une Scene de la St. Barthelemy" (1828); "Le Cardinal de Richelieu" and "Le General Moncey" (1835). Committee of the Privy Council, which consists of the Lord President of the Council, the Lord Chancellor, the Chief Justice, and Chief Baron, the Master of the Rolls, and Lords Justices. The Court of Appeal in Chancery, the Judges of the High Court of Admiralty and of the Court of Probate, and certain other persons nominated by the Crown. In ecclesiastical causes, Bishops who are Privy Councillors are members of the committee. The proceedings of this tribunal, which are always kept secret, and are not laid before the House of Lords, are now published. (3 & 4 Will. IV. c. 41; 6 & 7 Vict. c. 36). The Judicial Committee has authority in various other matters, as to which see Paxton, S. 2; Judicial Committee, S. 2. (Blackstone's Commentaries, ed.)

DENIZEN. Letters of Denization are now dismissed, aliens generally having recourse to the simpler and more advantageous certificate of naturalisation granted by the Secretary of State. (Austin, S. 1.)

DENIZEN is a genus of fishes belonging to the Family Sparidae. It has the following characters:—Body deep, compressed; dorsal fin, single; head large; teeth conical, placed in a single row, four in the front above and below, elongated, and curved inwards, forming hooks; teeth on the branchial arches, but none on the vomer or palatine bones; nose and suborbital space without scales; branchedioctous rays 6. There are several species of this genus.

D. vulgaris, the Four-Toothed Sparus, is regarded as a native of England; and on a single occasion, seems to have taken root in this country, and that by Mr. Donovan in 1805 off Hastings. It is a very common fish in the Mediterranean, and is the Dentex of the Romans. It is remarkable for the great length of the four anterior teeth in each jaw, which, together with a large mouth, enables him to take fishes from 20 to 30 pounds, and measuring 3 feet in length. Mr. Donovan's specimen weighed 16 pounds. "A more voracious fish," says Mr. Donovan, "is scarcely known; and when we consider its ferocious inclination and the strength of its formidable canine teeth, we must be fully sensible of the great ability it possesses in attacking other fishes even of superior size, with advantage. It is asserted, that when taken in the fisherman's nets, it will seize upon the other fishes taken with it, and massacre them dreadfully. Its swift swimming, it has been seen amongst to a considerable size. Willoughby observes that small fishes of this species are rarely taken, and the same circumstance has been mentioned by later writers. During the winter it prefers deep waters, but in the spring or about May it quits this retreat, and approaches the entrance of great rivers, where it deposits its spawn between the crevices of stones and rocks.

"The fisheries for this kind of Sperus are carried on upon an extensive scale in the warmer parts of Europe. In the manufacture of the Levant, the Levantine term of this fish is an object of material consideration, both to the inhabitants generally as a wholesome and palatable food when fresh, and to the mercantile interests of those countries as an article of commerce. They prepare the fish according to an old system, by cutting it in pieces, and packing it in barrels with vinegar and spices, in which state it keeps perfectly well for twelve months."

DENTINE. [Tissues, Organic, S. 1.]

DEODAND. Juries and judges having (as stated in the "Penney Cyclopaedia," vol. viii. p. 411) alike condemned this species of forfeitique, the law has been altered by the statute 9 & 10 Vict. c. 5, and deodands are now entirely abolished. (Miranda, S. 1. and Deodands (in Criminal Cases). The statute 11 & 19 Vict. c. 106 also contemplates with great care the most exact mode in which the depositions of witnesses are to be taken in criminal cases. The statute requires a deposition to be put in writing, to be read over to the witness, and to be signed by him. Unless these formalities are complied with, and the deposition has been taken in public, the accused, and he has had full opportunity of cross-examination, it is not admissible in evidence against him.

DEPOSITIONS (in Equity). Evidence is now taken in Chancery, as in other courts, by an officer of the court examining not by written interrogatories, but orally, in the presence of the parties, the witness being subject to cross-examination and re-examination. This new system, in imitation of that public examination of witnesses pursued in courts of common law, has not, however, prevented a general introduction, under the name of a Deposition, introduced as part of the practice of the Court of Chancery by the statute 15 & 16 Vict. c. 86. (Blackstone's 'Commentaries,' Mr. Kerr's ed., vol. iii. p. 520.)

DEPPING, GEORGE BERNARD, was born at Münster, May 11, 1784. Having completed his educational course, he visited Paris in 1809, when, forming acquaintances there, and observing the facilities which the city afforded for the prosecution of literary studies, he determined to make it his permanent residence. The rest of his life was spent there in the uneventful career of a busy littérateur.

For many years M. Deppping mainly occupied himself in preparing juvenile and popular works chiefly on geographical and zoological subjects, and laying the foundation of a natural history encyclopaedia. His first important original work was one written for a prize offered by the Institute on the 'Expedition Maritime des Normands en France au Dixième Siècle.' For this he was awarded the Prix de l'Institut in 1836. Among his other important works may be named—'Histoire de la Normandie,' 'Histoire de la Normandie,' from the Conqueror to the Incursions of the French with the Normans (1015 to 1040); 'Deodands, S. 1. of the French language. M. Deppping wrote many of these important articles in the "Biographie Universelle," 'L'Art de Vérité, pour tous et pour chacun' (vol. ii. i. iii. of the Collection des Documents Inédits de l'Histoire de France), 1840; (fig. 1835.)

formations, and that under certain circumstances these green bodies represent a germ, capsule, or sporangium, in which, by a process of division, various young *Closteria* come to be produced. The union of the cells of *Didymoparm Borri* is seen in fig. 1.

The process above described appears to be one entirely confined to the vegetable kingdom, as it has never been observed amongst unicellular organisms, which are regarded as exclusively animal.

The process of swarming is one which, although a few years ago its distinguishing feature would have been regarded as entitling the organism exhibiting it to a place in the animal kingdom, and hence the English naturalists regarded purely vegetable. It has been observed in many species of *Confervarum*, more especially in *Achlya prolifera* and *Conferva area*. The following is Mr. Agardh's account of this curious phenomenon in the latter plant. After describing the green matter in the joints, he says—"The granules of which it is composed detach themselves from the mass one after another, and having thus become free they move about in the vacant space of the joint with an extreme rapidity. At the same time the exterior membrane of the joint is observed to swell in one point till it there forms a little lamella, which is to become the point from which the moving granules finally issue. By the extension of the membrane for the formation of the lamella, the tender flaps of which it is, it is composed separating, cause an opening at the end of the joint, through which the granules escape. At first they lie in a body, but soon those remain, swimming in a much larger space, have much more difficulty in escaping; and it is only after impenetrable knockings (littibations) against the walls of their prison that they succeed in finding an exit. From the first instant of the motion, one observes that the granules or sporules are furnished with a little head, a kind of anterior process always distinguishable from the body of the sporule by its paler colour. It is on the vibrations of this head that the motion, as I conceive, depends; at least I have never been able to discover any cilia. However I will not venture to deny the existence of these; for with a very high power of a compound microscope one sees the granules surrounded with a hyaline border, as we find among the ciliate *Infusoria* on applying a glass of insufficient power. The sporules during their motion always present this head in front of their body, as if it served to show them the way; but when they cease to move, by bending it back along the side of their body, they resume the spherical form, so that before and after the motion one sees no trace of this head. The motion of the sporules before their exit from this point consists principally in quick dartings along the walls of the articulation, knocking themselves against them by innumerable shocks; and in some cases we are almost forced to believe that it is by this motion of the sporules that the lamella is formed. Escaping from their prison, they continue their motion for one or two hours; and retarding always towards the darker edge of the vessel, sometimes they prolong their wandering courses, sometimes they remain in the same place, causing their head to vibrate in rapid circles. Finally they collect in dense masses, containing innumerable grains, and attach themselves to some extraneous body at the bottom or on the surface of the water, where they hasten to develop filaments like those of the mother plant." This process, to which the name swarming has been given, has been observed by Mr. Raîsâ, Dr. Hassall, and others in various species of *Domesticum*, more especially in *Spherosps crista* and *Draparnaulia tensis*. No similar movements to these have been anywhere observed amongst the ova of the animal kingdom.

The presence of starch in the *Domesticum* is a third point raised on by Mr. Raîsâ as distinguishing the vegetable kingdom. The existence of this substance is easily ascertained by the well-known reaction of iodine upon it. Meyen first discovered this substance in the *Algae*, and Mr. Raîsâ and others have confirmed his observations. At the same time it should be stated that starch, although not found present in the tissues of the lower animals, has recently been detected in the brain of man by Mr. Brâk ('Microscope Journal', vol. ii. p. 103). This may lead to the discovery of the presence of this carbohydrate not only in the animal kingdom than has been hitherto supposed.

The following reasons are given by Mr. Dalrymple, after giving an account of the structure of *Closteria*, for placing the species of this genus amongst animals:—

1st. That while *Closterium* has a circulation of molecules greatly resembling that of plants, it has also a definite organ unknown in the vegetable world; in which the active molecules appear to enjoy an independent motion, and the parieters of which appear capable of contracting upon its contents.

2nd. That the green gelatious body is contained in a membraneous envelope, which, while it is elastic, contracts also upon the action of certain reagents, whose effects cannot be considered purely chemical.

3rd. The comparison of the supposed ova with cytoblasts and cells of plants precludes the possibility of our considering them as the latter, while the appearance of a vitelline nucleus, transparent hat molecular fluid, a chorion, or shell, determines them as animal ova. It was shown to be impossible that these eggs had been deposited in the empty shell by other *Infusoria*, or that they were the produce of some Enterosom.

4th. That while it was impossible to determine whether the vague motions of *Closterium* were voluntary or not, yet, the idea the author had formed of a sectorial apparatus for his classing them with plants.

On these reasons, Mr. Raîsâ remarks, that the peculiar organ—the terminal glochides—of the *Closteria* are as much vegetable as animal. That the throwing off of the contents of the cell through chemical reagents, is as much vegetable as animal. "If fresh water touches *Griffithia sectae*, the joints burst and split out their contents." That the supposed ova contain starch, and are therefore vegetable. That he cannot discover that the orifices at the extremities of some of the *Domesticum* are tubes, or that they possess a sectorial power.

---

*Fig. 1.* Didymoparm Borri, with the cells uniting to form the green matter. *Fig. 2.* Microstaria cereata. *Fig. 3.* Eubastia oblonga. *Fig. 4.* Xanthidium orbiculare. *Fig. 5.* The same. *Fig. 6.* Euthamia emarginata. *Fig. 7.* Closterium Lomrole. *Fig. 8.* Pediastrum simplex. *Fig. 9.* Pediastrum Borpurum. *Fig. 10.* Anhydratium foliatum.

The *Domesticum* are all of an herbaceous green color, and from this circumstance are easily discovered amongst the other microscopic beings with which they occur. They are mostly inhabitants of fresh water. Mr. Thwaites records two or three species from brackish water. They are remarkable for the very definite outline which their forms assume, especially in the genera *Microstaria* (fig. 2), *Eubastia* (fig. 3), *Xanthidium* (fig. 4), and *Pediastrum* (figs. 7, 8). Their most obvious characteristic however is their evident division into two valves or segments. The point of union between the two segments is in general very definitely marked. In *Pediastrum* and *Somedaemia* it is less obvious than other genera. It is at this point of union that the cell...
be found in great abundance on the line, which, if kept moist, will allow of the growth and development of these beautiful objects for many months.

The study of this family will undoubtedly repay the naturalist for years to come. Comparatively little is known of the species beyond the confines of Europe. The following is a catalogue of the genera found by Mr. Ralfs in the British Islands:

*Plant an elongated jointed filament. Sporangia orbicular, smooth.*

1. **Didymoprium**—Filament cylindrical. Two species.

2. **Didymoprium**—Filament cylindrical, or sub-cylindrical. Joints with two opposite or dentate projections. (Fig. 1.) Two species.

3. **Didymoprium**—Filament triangular, or quadrangular; joints connected by a thickened border. Two species. Three species.

4. **Didymoprium**—Filament transverse, or plai, with fornina between the joints. One species.

5. **Spharosoma**—Filament plane, margins incised or sinuated; joints with junction-glands. Two species.

Froed simple from complete transverse division, distinctly constricted at the junction of the segments, which are seldom longer than broad; sporangia spinnous or tuberculated, rarely if ever smooth.

6. **Microstegia**—Lobes of the segments incised or bidentate. (Fig. 2.) Thirteen species.

7. **Didymoprium**—Segments sinuated, generally, notched at the end, and with inflated protuberances. (Fig. 3.) Eighteen species.

8. **Comisia**—Segments in front view neither notched nor sinuated; in end view elliptic, circular, or cruciform. Two species.

9. **Xanthidium**—Segments compressed, entire, and spinous. (Figs. 4 and 5.) Six species.

10. **Arthrodema**—Segments compressed, and having only two spines or mucres. Two species.

11. **Staurastrum**—End view angular, radiale, or with elongated processes which are never geminate. Forty species.

12. **Didymoprium**—Segments angular, each angle having two processes, one inferior and parallel with the similar one of the other segment, the other superior and divergent. One species.

Froed simple, from complete transverse division, generally much elongated, never spinous, frequently not constricted at the centre. Sporangia smooth.

13. **Tetramorus**—Froed straight, constricted at the centre, and notched at the ends. Three species.

14. **Penteia**—Froed straight, scarcely constricted at the centre. Eight species.

15. **Cetesia**—Froed straight, much elongated, constricted at the centre. Truncate at the ends. Seven species.

16. **Cletesia**—Froed crescent-shaped or arcuate, not constricted at the centre. (Fig. 6.) Twenty-two species.

17. **Spirontia**—Froed straight, not constricted at the centre; endochrome spirally twisted. Two species.

18. **Anisomorpha**—Cells elongated, entire, fuscicolate. (Fig. 9.) One species. Six species.

Froed composed of few cells, definite in number, and not forming a filament. (Sporangia unknown.)

19. **Pediastrella**—Cells arranged in the form of a flattened star, their outer margin bidentate. (Figs. 7 & 8.) Eleven species.

20. **Scenedesmus**—Cells oblong or fusiform, entire, placed side by side in a single row, but during division into two rows. Six species.

(Ralfs and Jenner, British Desmidieae: Siabold, On Uninastic Plants and Animals, in Mic. Journal, 1853; Maneghini, On the Animal Nuciee of Diatomaceae, translated by Ray Society, 1854; A. Braun, On Rejuvenescence in the Plant, translated by Ray Society, 1854; Lindley, Vegetable Kingdom; Nageli, Gattungen einzelliger Algen physiologisch und systematisch bearbeitet, Zurich, 1848; Cohn, On the Natural History of Protococcus platense, translated by Ray Society, 1854.)
DIATOMACEÆ, OR DIATOMÆ, a group of organised beings which naturalists have placed in the animal and vegetable kingdoms, according as they have regarded their structures as most allied to the one kingdom or the other. These organisms consist of a single cell, and are remarkable for possessing a hard shell or frustule, which is composed of different materials, some of which remain permanent after its organic tissues have perished.

The following is a definition of this group of beings by one of the most recent writers on this subject:—Plant a frustule; connect it with an imperfect cell, and you have a bivalve siliceous epidermis. It exists in its own self, and its increase, by self-division; during which process the cell secretes a more or less siliceous connecting membrane. Reproduction, by conjugation, and the formation of sporangia. (W. Smith.)

The Diatomaceæ are endowed with the power of motion; and when this function was supposed to be peculiar to the animal kingdom, it is not to be wondered at that the first observers of these organisms referred them to the animal kingdom. Ehrenberg, in his great work on the Infusoria, Animalcules, and Corroborative of our knowledge of this family, has added to the forms that were already known. He regarded them, as well as the Desmidiceæ, and other beings which are now generally referred to the vegetable kingdom, as animals. The following are the principal points on which he relied for assigning to them this position:—

1st. The Diatomaceæ exhibit a peculiar spontaneous movement, which is produced by certain locomotive organs.

2nd. A large number of them have in the middle of the latest lamella, which is known as the valve of the frustule, a diatom which is known as the valve of the frustule, and which is composed of the Motile Organ, which is known as the valve of the frustule, and which is composed of the Motile Organ, which is known as the valve of the frustule, and which is composed of the Motile Organ, which is known as the valve of the frustule, and which is composed of the Motile Organ, which is known as the valve of the frustule, and which is composed of the Motile Organ, which is known as the valve of the frustule, and which is composed of the Motile Organ, which is known as the valve of the frustule, and which is composed of the Motile Organ, which is known as the valve of the frustule, and which is composed of the Motile Organ, which is known as the valve of the frustule, and which is composed of the Motile Organ, which is known as the valve of the frustule, and which is composed of the Motile Organ, which is known as the valve of the frustule, and which is composed of the Motile Organ, which is known as the valve of the frustule, and which is composed of the Motile Organ, which is known as the valve of the frustule, and which is composed of the Motile Organ, which is known as the valve of the frustule, and which is composed of the Motile Organ, which is known as the valve of the frustule, and which is composed of the Motile Organ, which is known as the valve of the frustule, and which is composed of the Motile Organ, which is known as the valve of the frustule, and which is composed of the Motile Organ, which is known as the valve of the frustule, and which is composed of the Motile Organ, which is known as the valve of the frustule, and which is composed of the Motile Organ, which is known as the valve of the frustule, and which is composed of the Motile Organ, which is known as the valve of the frustule, and which is composed of the Motile Organ, which is known as the valve of the frustule, and which is composed of the Motile Organ, which is known as the valve of the frustule, and which is composed of the Motile Organ, which is known as the valve of the frustule, and which is composed of the Motile Organ, which is known as the valve of the frustule, and which is composed of the Motile Organ, which is known as the valve of the frustule, and which is composed of the Motile Organ, which is known as the valve of the frustule, and which is composed of the Motile Organ, which is known as the valve of the frustule, and which is composed of the Motile Organ, which is known as the valve of the frustule, and which is composed of the Motile Organ, which is known as the valve of the frustule, and which is composed of the Motile Organ, which is known as the valve of the frustule, and which is composed of the Motile Organ, which is known as the valve of the frustule, and which is composed of the Motile Organ, which is known as the valve of the frustule, and which is composed of the Motile Organ, which is known as the valve of the frustule, and which is composed of the Motile Organ, which is known as the valve of the frustule, and which is composed of the Motile Organ, which is known as the valve of the frustule, and which is composed of the Motile Organ, which is known as the valve of the frustule, and which is composed of the Motile Organ, which is known as the valve of the frustule, and which is composed of the Motile Organ, which is known as the valve of the frustule, and which is composed of the Motile Organ, which is known as the valve of the frustule, and which is composed of the Motile Organ, which is known as the valve of the frustule, and which is composed of the Motile Organ, which is known as the valve of the frustule, and which is composed of the Motile Organ, which is known as the valve of the frustule, and which is composed of the Motile Organ, which is known as the valve of the frustule, and which is composed of the Motile Organ, which is known as the valve of the frustule, and which is composed of the Motile Organ, which is known as the valve of the frustule, and which is composed of the Motile Organ, which is known as the valve of the frustule, and which is composed of the Motile Organ, which is known as the valve of the frustule, and which is composed of the Motile Organ, which is known as the valve of the frustule, and which is composed of the Motile Organ, which is known as the valve of the frustule, and which is composed of the Motile Organ, which is known as the valve of the frustule, and which is composed of the Motile Organ, which is known as the valve of the frustule, and which is composed of the Motile O
spread themselves along the membrane which is embraced by the new valves, and there result two half-new frustules bound together by the connecting membrane, generated during the process we have described.

"During the healthy life of the Diatom the process of self-division is being continually repeated; the two half-new frustules at once proceed to divide again each into two frustules, and thus the process continues. I have been unable to ascertain the time occupied in a single act of self-division, but supposing it to be completed in twenty-four hours, we should have, as the progeny of a single frustule, the amazing number of one thousand millions in a single month; a circumstance which will in some degree explain the sudden or at least rapid appearance of vast numbers of these organisms in localities where they were but a short time previously either unrecognized or only sparingly diffused." (Smith, p. 25.)

The structure of the silicious portion of the Dictomaceae is the most remarkable part of their organisation. The following is Meneghini's account of this organ.

"Every Diatom is formed of a silicious shield and a soft substance therein contained. According to Kützing, this shield consists of pure silica, or, in some cases, perhaps, of silica combined with alumina. Nägeli further says that the silica is deposited in the outside of an organic membrane, which he believes to be of a vegetable nature. In fact, an organic membrane ought to exist, for the silica could not become solid except by crystallizing or depositing itself upon some pre-existing substance. On the other hand, we cannot admit, with Nägeli, that it has been deposited externally for in many genera, and especially in the Achnanthes, the silicious shield is covered with a very delicate, delicate membrane, itself containing silica, as is proved by its soon taking on an adamantine lustre of fire and acids. Therefore, comparing this shield with other organic formations, whether animal or vegetable, containing in like manner either silica or some other so-called mineral element, we may reasonably consider it to be formed of an organic tissue per se. It occurs either in the wall of a single cell, as is seen in the epidermal cells of many plants, or within minute cells, as in various plants and animals. The action of heat, or of acid, in these cases, destroys the organic matter and leaving the silica unaltered, does not alter the apparent form of the organ, because the skeleton remains unaltered.

"Externally to the shield Kützing observed a thin stratum which he denominated cement, which may be made visible either by desiccation or by calcination; and produces either a simple opacity, or lines, points, and maculae, sometimes irregularly disposed, sometimes regularly. He supposes it to be a silicate of iron or of alumina. Independently of the chemical materials which it may contain, this outside integument seems to serve the more important function of allowing, without resorting to the means indicated by Kützing, I observe it to be constant, not merely in the species enumerated by him, but also in many others, and I could almost assert that it exists in all. For to me it appears to correspond with that fine membrane of the Achnanthes, above mentioned, which, according to Kützing's own observations, is always visible whenever the two new individuals (into which every Diatom is resolved in its multiplication by division) (conspicua) begin to separate. The line and points supposed to belong to the subjacent shield belong very frequently to this kind of covering.

The shield itself is formed of at least four pieces, or valves, united together in a four-sided figure—a tetragon. The mode of union is unknown. But the existence of a kind of articulation which permits an opening and closing, like the valves of a shell-fish described by Corda in a species of Sarracina, has been denied by other observers. Be this as it may, whether spontaneous after death or induced by external means, this separation does take place in a regular manner. Now, if we suppose an organic cell with a wall permeated by silica, and with a four-sided figure, we can easily suppose that all the sides will mechanically support each other. Moreover, we shall meet with numerous forms by a different kind of analogy, namely, that with solid animal tissues belonging either to the internal or the external segment.

The four valves are equal in length, but in many species and genera one pair exceeds the opposite pair in breadth. In order to establish a uniform language it is convenient to term those primary valves or surfaces which exhibit along the middle the line of division in the act of decadution, which, since it is formed here in a normal plane, is parallel to the other two surfaces, denominated lateral. Along the primary surfaces we frequently see longitudinal lines, which terminate at the two extremities in small apertures. From their internal surface there project into the cavity linear or curved variously formed but always longitudinal; these are termed vitre.

The lateral surfaces have frequently a round aperture of greater or smaller size in the centre, and from this a finer external line is continued. This fissure either remains itself gradually or expands into a circular aperture. When this occurs each of these surfaces is divided into two distinct valves. On these lateral surfaces we observe the striae, lines, and transverse costae, no less admirable for their beautiful appearance than for their constant regularity in number, direction, and proportion. When many individuals are united together to form one compound being, like a polyp for instance, it is always by the lateral surfaces that they are彼此, and since all other characters at times fail, we can affix to them the denomination 'lateral' from this principal one.

Besides the vitre before mentioned, in some general (Biddulphia, fig. 15, Climacospherina, Terpinia) there are other vestiges in their internal cavities; these are variously arranged.

These essential peculiarities of the shield may perhaps
be regarded as indicating a complex structure, very different therefore from what would be prescribed by a simple cellular wall. Ehrenberg deduces from it an argument to compare it with the shell of 

*Holocyclus.* The *Arelithae* may be cited among the Infusorians, Kützing states, in reply, that among vegetable cells there is found a peculiar conformation of the walls, with prominences, depressions, points, lines, papilles, and perforations, disposed in a regular manner; he refers to grains of pollen, as an instance. He might have added the more appropriate from the Pointed Bacillus, which would be very closely allied to the *Diatoms,* if the latter, like the former, could be referred to the vegetable kingdom. If not equal in constancy and regularity, the *Diatomacee* display a greater degree of complication; and we must remember the different nature of the wall in the vegetable cell, when lime or silica predominates, the wall becomes uniform and regular (I) (uniforme et irregolare).

The silicaceous epidermis presents an extraordinary variety of forms, which in every genus and species offer the best possible means of distinction and identification: striæ, or lines frequently moniliform, dots arranged in a radiate or concentric manner, and minute divisions presenting perfectly hexagonal outlines, are amongst the most frequent occurrences. *Diatomacee* are of the most minute size, and the wall, as supposed by Ehrenberg and Kützing, these foraminæ are also denied by Schleiden. Mr. Smith denies also that the valves are externally covered with any organic membrane.

The delicacy of the markings on many of the *Diatomacee* render them objects peculiarly adapted for testing the powers of the object-glasses of the microscope. The following table, drawn up by Messrs. Sollitt and Harrison of Hull, to whom microscope, indubitably few hours, and the first pointed out this nature of these. Mr. Smith says, "I am disposed to regard them all as modifications in the arrangements of the silex of the valve, arising from the mode of development peculiar in each case to the membrane with which the silex is con- tained." He also denies the existence of perforations in the valve, as supposed by Ehrenberg and Kützing. These foraminæ are also denied by Schleiden. Mr. Smith denies also that the valves are externally covered with any organic membrane.

The *Diatomacee* possess the power of moving. "The cells have no special organs for these movements. But as, in consequence of their nutritive processes they take in and give out fluid matter, the cells necessarily move when the attraction and the emission of the fluids is unequally distributed on parts of the surface, and is so active as to overcome the resistance of the water. This motion consequently is observed more particularly in those cells which, in consequence of their taper forms, easily pass through the water; these cells moreover move only in the direction of their long axis. If one half of a spindle-shaped or ellipsoidal cell chiefy or exclusively admits material, the other half, on the contrary, giving it out, the cell moves towards the side where the admission takes place. But, as in these cells both halves are physiologically and morphologically exactly alike, so it is that it is first the one and then the other half which admits or emits, and consequently the cell moves sometimes in one, and sometimes in the opposite direction."

This is perhaps as satisfactory an explanation of these movements as can be given in the present state of our knowledge. All observers agree that they can find no evidence to support Ehrenberg's notion of a pedal or mantle organ projected from the interior of the silicious shield. The Rev. W. Smith has also detected ciliaison in the *Diatomacee.* "A distinct movement," he says, "of the granular particles of the endochrome, closely resembling the ciliaison of the cell-contents in *Clathriona Lamellata,* noticed by Mr. Ralfs [Desmids], and which I have frequently detected in the same species, has occasionally fallen under my notice in some of the larger forms of *Diatomacee.*" He has observed it in *Surirella distorta.* (Fig. 4.) "I call this circulation," he continues, "has not however the regularity of movement so conspicuous in the *Diatomacee,* and is of too ambitious a character to furnish data for any very certain conclusions, save one, namely, that the Diatom must be a single cell, and the entire division of its contents, such as have been alleged to occupy its interior; since the endochrome moves freely from one portion of the frustule to another, approaching and receding from the central nucleus, unimpeded by any intervening obstacle.

The *Diatomacee* are therefore abundant and extensively distributed of unicellular organisms. They are found in the ocean, at the mouths of rivers, in brackish waters, in rivers, lakes, ponds, ditches, pools, and claterra. In fact, wherever a few drops of water are allowed to remain exposed to the air, we may expect to find forms of *Diatomacee.* Their forms are not less abundant than their presence. In the first volume of his *Synopsis of the British Diatomacee,* the Rev. W. Smith has described upwards of 230 species, and the *Diatomacee* of the Thames and its tributaries, *i.e.* few species known in Great Britain is considerably above 800. The facility with which their forms are preserved, give to these objects a great advantage, and a handful of sand from the sea or mud from a river in the most remote district of the world may be made to yield a vast number of new and abundance of new forms. They occur in great abundance in the river Thames, and its mind affords a large variety of the frustules of those which have ceased to exist. In a few drops of water from the *Excursion of the Thames and Other Water,* by Dr. Lancaster and Redfern, upwards of forty species were observed.

The mode of collecting living specimens for observation is simply to allow the water in which they exist to stand for a few hours in the sunlight, when, by carefully cleansing the vessel, a portion of the water, a portion remains at the bottom of the vesel more turbid than the rest, and which generally contains in large numbers the objects sought for.

In describingshowers of coloured dust which have occurred in various parts of the world, Ehrenberg has demonstrated that various forms of *Diatomacee* have been found present. In some seasons these organisms occur in such numbers in the waters of rivers as to give to their banks a peculiar physical aspect. In the autumn of 1861 the stones and pebbles in the nearly dried-up bed of the Annan, in Dumfriesshire, presented an appearance as though they were white-washed. The substance which gave the stones this appearance could be scraped off, and looked like some form of calcareous matter. One of these pebbles was observed to pass through the mouth of a fresh-water mollusc. Lankester found that it consisted entirely of the silicious shields of a species of *Syndra.* (Fig. 5.) In the first volume of the new series of the *Transactions of the Microscopical Society,* Mr. Shadbolt has given an account of the examination of portions of mud given him by Mr. Pick from the Natal. This mud was recent, and from the nature of the specimens in it, Mr. Shadbolt thinks it probable that it was obtained not far from the mouth of some river. In this mud was made out fifty-five distinct species of *Diatomacee,* twenty of which has described as entirely new species. In the *Microscopical Journal* for July, 1853, Mr. Brightwell of Norwich has described nine new species of one genus—*Triceratium.* Six of these are recent. He says, "We have received near the Tamar a recent mud obtained from the near surface of the large sea-shells of the genera *Hipponus* and *Haliothis* before they have been cleaned. Many of them in this state are covered with small zoophytes, minute algae, and other parasites..."

One of the most singular positions in which *Diatoms* are found is in the guano brought from America and Africa. They have been observed by many observers to be frequently found by fish and subsequently by birds; their shields, however, have been able to withstand this double process of digestion, and they are found in large numbers in every pure specimen of guano. Some of the forms which have been preserved in this natural manner have been found amongst the most singular of the family. It has been suggested that the silex thus introduced into the guano may contribute to its fertility, as it is well known that this sub-
instance is present in the stems of all our cereal grasses, and is necessary to their growth.

It may be confidently said that, for the time being, the results of the present investigation will be found in many of the older formations of the earth's surface. This is very extensively the case; although it may be doubted whether, from the fact of their being occasionally found in igneous rocks, that they were not found there by the action of water. The regular occurrence of very small animals is, however, an indication whichEbeneberg has been able to detect in their presence in some of the earliest rocks of the Palaeozoic series. How *Diatomaeeas* may be present in igneous rocks has been suggested by Dr. Hooker. During his voyage with the *Erebus* in the Antarctic Ocean he says, 'This order occurred in such countless myriads as to stain the sea everywhere of a pale ochreous-brown, in some cases causing the surface of the ocean, from the locality of the ships, as far as the eye could reach, to assume a pale-brown colour.' This immense increase of organisms persisting are producing a sub-marine deposit, or bank, of vast dimensions, resting on the shores of Victoria Land, and hence on the sub-marine flanks of Mount Erebus, an active volcano upwards of 12,000 feet high. Knowing as we do that *Infusoria*, *Diatomaeeas*, and other organic constituents, enter into the formation of the peumice and sabes of other volcanoes, and are still recognisable in their minerals, it is perhaps not unreasonable to conjecture that the subterranean and subaqueous forces which kept Mount Erebus in activity, may open a direct communication between this *Diatomaeeas* deposit and its volcanic fires.

Ehrenberg has described a large number of forms of *Diatomaeeas* from the oolite, cretaceous, and other secondary rocks. Amongst the most interesting in this connection is the description by Sir Robert Schomburgk in the 'Reports of the British Association for 1847, furnished him with an entirely new group of beings apparently related to this family. The following is Sir Robert's account of this discovery:—

'In the white marls and other rocks of Scotland district, Professor Ehrenberg of Berlin discovered a new and great group of siliceous-shelled animals, which, in a report read before the Royal Academy of Sciences, he described as *Polygynites* and *Polythalamis*. These animals are remarkable and articulate shells which cover these animals distinctly. They possess large apertures at the extremity of the body, which has no analogy among plants, but occur very commonly among animals. These siliceous loricated organic forms in the rocks in Barbadoes differ alike from *Polygynites* and *Polythalamis*, but develop an important relation to these two groups, which Professor Ehrenberg considers, not upon any general arrangement of animals possessed of vessels but with a heart and intesinal canal, and provided with a simple tubular intestinal canal. The forms developed in this highest degree in that direction would be *Holothuria* and *Bolinoides*.

The minute forms of organic life in the rocks in Barbadoes, as far as investigated by Professor Ehrenberg in February, 1847, consist of the following groups:—

*Polygynites*...392
*Polygynites*...18
*Polythalamis*...27
*Polythalamis*...7

Of these more than 300 are new forms.

The great discovery of the *Polygynites*, which might be almost called a new class, since they amount to upwards of 200 species, a larger number of specific forms than is contained in some classes of animals, may guide to form the idea of the geological age of the rocks in Scotland district, by comparing these forms with similar fossil animals from rocks upon the age of which geologists have agreed. Ehrenberg has been able to compare the *Polygynites* from the rocks of Barbadoes resemble more the animals from rocks of the secondary period than the tertiary.

Amongst the varieties of quartz rock the mineralogist recognises, under the name of tripli and polishing powder, certain white and pearly forms of quartz. On placing these substances under the microscope they are found to be entirely composed of the silicious frustules of *Diatomaeeas*. The polishing powder or slate (polish-sliers) found at Bilu in Bohemia is used for the purpose of producing a polish on fine surfaces. The regularity and beauty of the frustule of the Diatom will adapt them to this purpose.

Another deposit in which the *Diatomaeeas* have been found in great abundance is the Bergmei of Sweden. (Bramant, p. 1.) The Diatoms found by Ehrenberg in this formation are principally species of *Navicula*. (Fig. 6.)

Amongst the tertiary deposits, beds of *Diatomaeeas* are very common. They have been observed in Italy, in Germany, and in several of the States of America. 'The city of Richmond in Virginia is said to have been built upon a stratum of *Diatomaeeas* remains, 18 feet in thickness.' (Smith, Professor Gregory of Edinburgh has recently described, in the 'Transactions of the Microscopical Society,' a *Diatomaeeas* earth, discovered about two years ago by the Duke of Argyll in the Lake of Mull. It constitutes a bed, resembling marl in appearance, lying in a rough piece of ground between Loch Baa and the sea. The lake is about 30 feet, the land about 40 feet, above the sea-level. At one part there is a hollow, which in winter used to become a small loch, in summer only a stagnant pool, and in draining this the bed of marl was discovered. The bed rests upon gravel, which appears to belong to the diluvial period, and the *Diatomaeeas* earth is probably of recent origin. Professor Gregory has excavated the bed with great care, and has given a list of upwards of 130 species, which he has been able to make out ('Quarterly Microscopical Journal,' January, 1854). Of these upwards of twenty are altogether new species, or species that are new in a British locality.

From these facts it appears that the subject of fossil *Diatomaeeas* promises an almost boundless field for further inquiry. It appears that we may say of these organisms what we can say of no other family or group of organised beings, that once created they exist for ever. Myriads of species of soft-bodied animals have perished, never to be recognised, but each individual cell of the Diatom leaves its silicious wall as a record of its existence—a record that the ordinary forces of nature seem to have little or no power in obliterating.

We now turn to the subject of arrangement. It would be of course impossible here to give any account of individual species, and systematic arrangement are being constantly modified by new discoveries. The following is an arrangement of the families or tribes by Kitting:—

**Tribe I. Striates.**

Order I. Automatace.

Without a central opening on the secondary valve.

* Transverse strie unbroken.

Family 1. Unstricte.
Family 3. Fragilartieri.

**Strie broken (interrupted) in the median line.

Family 5. Surstricte.

Order II. Siatomatace.

With the central opening.

* Monostriate.

Having a median aperture on only one of the two secondary surfaces.

Family 6. Cocoonostric.
Family 7. Acho.nostric.

* 8 Diatomatace.

With a median aperture on each secondary surface.

Family 8. Cymbellicr.
Family 9. Cymphephonata.

**Tribe II. Violate.**

Order I. Automatace.

Without central opening on secondary side.

Family 11. Lichomophora.
Family 12. Strictelata.
The Rev. W. Smith, in his "Synopsis of the British Diatomaceae," gives the following arrangement of the genera:

**Sub-Tribe I. Frustules naked; not imbedded in gelatine or inclosed in membranaceous tubes.**

### Sub-Tribe 1. Connecting membrane detached; frustules solitary, or during self-division in pairs; rarely in greater numbers, adherent or free, dispersed, or aggregated into a mucous stratum.

**22 Genera—**

- *Epithemia* (fig. 19). 16 species.
- *Euxanthea* (fig. 1). 7 species.
- *Cymbella* 6 species.
- *Amphora* 8 species.
- *Cocconeis* 6 species.
- *Eucocconeis* 1 species.
- *Esperdus* (fig. 2). 5 species.
- *Actinocyclus* 1 species.
- *Arachnoidiscus* 1 species.
- *Triceratium* (fig. 3). 2 species.
- *Cyclotella* 4 species.
- *Campylodiscus* 7 species.
- *Surirella* (fig. 4). 20 species.
- *Trybionella* 6 species.
- *Gymnosulcia* 2 species.
- *Nitzchia* 23 species.
- *Amphipora* 5 species.
- *Amphipleura* 5 species.
- *Navicula* (fig. 6). 26 species.
- *Pennularia* 24 species.
- *Stauronella* 10 species.
- *Pleurosigma* (fig. 7). 26 species.

**Sub-Tribe 2. Connecting membrane persistent; frustules after self-division attached by a gelatinous cushion, or dichotomous stripes.**

- **7 Genera—**
  - *Squerna* (fig. 5). 24 species.
  - *Doryphora* 2 species.
  - *Cocconeis* (fig. 8). 4 species.
  - *Gemmophora* (fig. 9). 12 species.
  - *Podolenia* 5 species.
  - *Rhizopleura* 3 species.
  - *Lichemomenta* 9 species.

**Sub-Tribe 3. Connecting membrane evanescent, or obsolete; frustules after self-division united into a compressed filament.**

- **12 Genera—**
  - *Meridion* (fig. 10). 2 species.
  - *Bacillaria* (fig. 11). 1 species.
  - *Humasonida* 7 species.
  - *Odontidium* 4 species.
  - *Denticula* 4 species.
  - *Fragilis* 3 species.
  - *Encocoma* 1 species.
  - *Achnanthes* (fig. 12). 6 species.
  - *Diademia* 3 species.
  - *Rhodonesma* 2 species.
  - *Scaphidium* (fig. 13). 1 species.
  - *Tetragynia* 1 species.

**Sub-Tribe 4. Connecting membrane persistent; frustules after self-division united into a zigzag chain.**

- **6 Genera—**
  - *Diatoma* (fig. 14). 4 species.
  - *Grammonobaculum* 2 species.
and curious books at extravagant prices, was advancing to a height which it had never before attained in England or elsewhere. It reached its culminating point at the celebrated sale of the library of the Duke of Roxburghe, in June 1912, where a copy of an early edition of Boccaccio, printed by Valla in 1471, and later owned by the Marquis of Blandford, afterwards Duke of Marlborough, for the sum of £2260; and it was afterwards discovered that an imperfect copy of the same book was in the Sunderland library at Blenheim, at the very time of the purchase, but had three times been sold since it was first mentioned in the catalogue.

Dr. Dibdin proposed, at a dinner party at Baron Bolland's, even before the Valdarker was sold, the establishment of a club, to dine together in honour of Bibliography. The club was established under the name of the Roxburghe Club—a name which, from this time forwards, the vice-president of the club adopted the rule that each of its members should every year reprint a book, to be presented to every member; and this practice seems to have led to the establishment of the numerous printing and publishing clubs now in existence, more liberal in their regulations than the original. The rise and progress of the bibliomaniac was stimulated and recorded by different publications of Dr. Dibdin: an 'Introduction to the Greek and Roman Classics,' in 1802; a dialogue, entitled 'Divorce from the World,' which was translated into Italian by Sbracia, in 1803; the 'Lectures on the English Enlargements, in 2 vols., in 1811; and the 'Bibliographical Decameron' in three large vols., in 1817. A new edition of Ames's 'Typographical Antiquities' was also commenced by him, and in 1816 was published in four vols., in 1819; and a minute account of the rare books in Earl Spencer's library, under the title of the 'Bibliotheca Spenceriana,' which occupied four volumes, and was extended by the 'Édites Alitheriane,' a description of Earl Spencer's seat at Althorp, and the arrangement of his library purchased by him; in the whole, seven volumes. In 1815, Dr. Dibdin made a tour abroad, to purchase books for the same patron, and the result was, a 'Bibliographical, Antiquarian, and Picturesque Tour in France and Germany,' 3 vols. 16mo, 1818. Dibdin also published his 'Decameron' and the 'Tour,' present beautiful specimens of typographv and engraving, produced at an expense which the author was never weary of proclaiming. In 'The Library Companion;' or, 'A Compendium of the Cambridge Oratory and the Choice of a Library' (1834), he apparently aspired at producing something of more general and permanent use; but the result was disastrous. The flippant and frivolous character of his remarks, and the inaccurate and superficial character of his information, were commented upon in so severe a tone by some of the leading reviews, in particular the 'Quarterly' and the 'Westminster,' that his reputation never recovered the shock. In the preceding year he had obtained permission of Earl Spencer, his first patron, to enter the library, and afterwards to be appointed to the rectory of St. Mary's, Bryanston Square, London; and his publications for some years were chiefly of a theological character. He retired to the field of English literature, and was for a short time the Editor of the London Literary Journal (3 vols. 1836), and in his 'Bibliographical, Antiquarian, and Picturesque Tour in the Northern Counties of England and in Scotland' (3 vols. 1838). He also made, not long before his death, a tour in Belgium, of which he also intended to publish an account. He died on the 10th of November, 1847, after a long illness, of paralysis of the brain. His latter years had been much clouded with pecuniary difficulties.

The most important of the publications of Dr. Dibdin have already been enumerated, but it will be necessary to recur to some of them to afford a fuller notion of their character. The most important is the 'Typographical Antiquities of Great Britain.' The meritorious work of Ames on that subject, facing to an account of all the books printed in England from the introduction of the art to the year 1600, had been expanded from one volume to three by Herbert, who made such extensive additions that the work might justly be regarded as his own. Dr. Dibdin's work was full room for extensive improvement on Herbert—a very similar alteration even in the arrangement would have much increased its value to nearly all who consulted it. The titles of the books are disposed under the names of the printers: had they been arranged, according to his 'Annals of German Literature,' in the plain order of date, a host of particulars would have presented themselves in combination which are now scattered and inacceessible. It would have been far from uninterseting to observe what books issued from the press in England during the year in which Henry broke up the monasteries, in which Mary lighted the fires of Smithfield, or in which Shakspeare first came to London. Dibdin has preserved the old arrangement, and has so much added to it, that the reader, who desires to know the contents of his edition, which was left imperfect, carry the record no further than the middle of the second volume of Herbert's three. Some of the matter which he has added is of interest, in particular his more minute account of the productions of marriage, and of our book-collectors. Dr. Dibdin is the only one of the book-collectors of the 18th century, illustrated with their portraits, which have nothing whatever to do with the history of printing in the 16th and 17th centuries. Much too of the additional matter for which the work was undertaken, has been taken from notes which Herbert had prepared for a second edition, and inserted in a copy of his work which is now in the British Museum. It is to be hoped that the whole subject will be resumed ere long by some competent scholar, with the numerous additional materials now at his command in our public libraries, when, with some industry and intelligence, a work may be produced which will interest not only the bibliographer but all who have a tincture of feeling for literary matters. The 'Bibliotheca Spenceriana,' from which, indeed, the whole of the latter part of this volume is taken, is another instance of the peculiar relationship of the work to the public in general, is often used as a work of reference: but those who have consulted it will find it vastly different from the attempt at it. The whole of the latter part consists of a book too little of the scholar and the man of letters, and too much of the bookseller and the bookbinder. The width of the margin, and the kind of leather in which a book is coated, astonish as much of his state no less than the accident which all copies of the book have in common. The 'Decameron' is by far the best of Dr. Dibdin's works, as comprising the least of detail and the most of anecdote; and it is written in many portions with a degree of care and spirit often wanting in his other works. The 'Reminiscences' afford singular proof that, although the author of an 'Introduction to the Classics,' his acquaintance with some of whom was of a very temporary character, he was acquainted with all of the bibliographical works abound with much that the reader wishes away, they are indispensable in any large library of English literature. His other productions, which are numerous, are 'Dichrote,' and 'Reminiscences.'

DICHROITE. [MINERALOGY, S. I.]

DICK, THOMAS, LL.D., was born in 1772. He was educated for the Christian ministry in connection with the Wesleyan Church of Scotland, and was a preacher in connection with that body in the early part of his career, but it is as a popular writer on physical science that he is best known to the world. The works by which he first became generally known were the 'Christian Philosophy of Religion,' in 1819, followed by works on the 'Improvement of Society by the Diffusion of Knowledge,' the 'Mental Illumination of Man,' 'The Philosophy of a Future State,' 'A Treatise on the Solar System,' 'Celestial Scenery,' 'The Sidereal Heavens,' 'The Practice of Astrology,' 'Prophetic and Christian Benevolence,' contrasted with Covelunoonism,' written in competition for the prize which was conferred on Mr. Harris for his work, entitled 'Mammon: or Covetousness the Sin of the Christian Church.' Dr. Dick was a man of unimpeachable integrity and disposition, who devoted himself to labour perseveringly for the public instruction, although his immediate reward was but small. His principal works were reprinted at low prices, and had extensive circulation, especially among the working classes, from which he derived his support. A public subscription on his behalf, as an acknowledgment of the benefits he had conferred upon society, was projected a few years since by some of his admirers,
but realised a very small amount, most of it being raised in the town of Dunedine, where the subscription was commenced. Dr. Dick's works have been reprinted and very extensively sold in the United States. Dr. Dick resided in the small village of Trinity-Bay, on the left bank of the river Tay, in Forfarshire. Besides instructing the pupils by his pen, Dr. Dick had been in the habit of accepting occasional appointments to preach in neighbouring churches, and also to deliver popular lectures on scientific subjects. A few years ago he moved to New Zealand, where he was occupied in the advancement in the advancement of popular science. He died July 20, 1857.

DICTYOGNIS, a class of plants, proposed by Lindley, and adopted in his 'Vegetable Kingdom.' It embraces a number of peculiarly marked species, belonging to the classes of

Exogens and Endogens. They have a monocotyledonous embyro, but they also have a broad net-veined foliage, which usually disarticulates with the stem. The following are the natural orders of Dicthyogynae:—

Placenta saxifraga, Carpels uniseriata, Perianth free, Carpels 00; one seeded.

Carpels bisexual. Perianth adherent.

DIDYMIUM, a generic name used by Mr. Loddiges, [Chemistry, S. 1.]

DIDYMOPHUM, a generic name used by Mr. Loddiges, [Chemistry, S. 2.]

DIEGO, SAN. [Canada, S. 2.]

DIGINITE, a native Sulphurpet of Copper.

DILMAN, a town in Perú, is situated on the caraván route from Tabriz to Erzerum, 70 miles W. from Tabriz, 10 miles W. from the north-west angle of Lake Urmiyeh, and has about 16,000 inhabitants. It is situated in the wide and fertile plain of Selmas, which stretches westward from the lake to the base of the Kurdish Mountains. The town is surrounded by gardens and orchards, and has clean streets. The plain about it is inhabited by Nestorians, Armenians, Catholics, Kurdish Leks, and Russian emigrants. About 4 miles to the westward is the old town of Dilman, a great portion of which is in ruins. From the number of mounds in the district, and the ruins of buildings in the immediate environs, it appears to be of considerable extent, and it is described by St. Martin as being a very ancient Armenian city. (Colonel Sheil, in London Geographical Journal, vol. vi.)

DINORNIS, a genus of birds probably extinct, the remains of several species of which have been found in New Zealand.

In November, 1839, Professor Owen exhibited, at a meeting of the Zoological Society of London, the fragment of the shaft of a femur, 6 inches in length, and 5½ inches in its smallest circumference, with both extremities broken off. This bone of an unknown struthious bird of large size, presumed to be extinct, was put into the Professor's hands for examination, by Mr. Rule, with the statement that it was found in the neighbourhood of Wellington, the capital of the island, that it belonged to a bird of the eagle kind, which has become extinct, and to which they gave the name Movie or Moa. Similar bones, it was said, were found buried on the banks of the rivers. After a minute description of the bone, Professor Owen made the following statement:—'There is no bone of similar size which presents a cancellous structure so closely resembling that of the present bone as does the femur of the Struthios, and it is placed in the ostrich at the middle of the shaft, where the peristyles of the medullary or rather air-cavity, are smooth and unbroken. From this difference I conclude the struthious bird indicated by the present fragment to have been a heavier and more stupid creature than the ostrich, and its femur, though its whole leg, was shorter and thicker. It is only in the ostrich's femur that I have observed superficial reticulate impressions similar to those on the fragment in question. The ostrich's femur is subcomprised, while the present is cylindrical, approaching in this respect nearer to the femur of the emu; but its diameter is one-third greater than that of the largest emu's femur with which I have compared it. The bones of the great Pelecanus, in the extremity of the shaft, are solid throughout; those of the preceding, proceeding from a cancellous structure like the present bone. The cancellous nature of the mammiferous long bone is of a much finer and more fibrous character than in the fossil. Although I speak of the bone under this view, there can be no doubt that it presents the characteristics of a true fossil; it is by no means mineralised; it has probably been on or in the ground for some time, but still retains most of its animal matter. It weighs 7 ounces 12 drachms avoidopris.'

The discovery of a large struthious bird in New Zealand is one of peculiar interest, on account of the remarkable character of the existing Fauna of that island, which still includes one of the most extraordinary and anomalous genera of the struthious order; and because of the close analogy which the event indicated by the present relic offers to the extinction of the Dodo of the island of the Mauritius. So far as judgment can be formed of a single fragment, it seems probable that the extinct bird of New Zealand, if it be certainly of the extant, has the legs, and nearly resembling those of the Dodo than of any of the existing Struthiones. Any opinion however as to its specific form can only be conjectural. The femur of the Stilt-Bird (Himantopus) would never have revealed the anomalous development of the bones of the legs. The conclusions of my skill in interpreting an osseous fragment may be credited, I am willing to risk the reputation for it on the statement that there has existed, if there does not now exist, in New Zealand, a struthious bird nearly if not quite equal in size to the ostrich.'

It was not long before an opportunity occurred of testing this very remarkable statement, and of proving the sagacity of the naturalist who had thus staked his reputation upon his conviction of the truth of the general principles of the science of comparative anatomy. Professor Owen received a communication from the Rev. W. Cotton describing several other remains of animals of the same kind, and in 1843 a collection, comprising vertebrae and bones of the hinder extremities, pointed to some 20 feet. The other bones, which I was granted by the Rev. W. Williams to the dean of Westminster (Dr. Buckland); and in 1846 many specimens were sent to England by Dr. MacKellar, Mr. Percy Earl, and Colonel Wakefield. These were placed in the hands of Professor Owen, and form the subject of his first and second 'Memoirs on the Dinornis,' in the 'Zoological Transactions,' vol. iii.

In these Memoirs Professor Owen pointed out that the bones which had been thus sent over from New Zealand had contained of no less than twelve of these remarkable group of birds, which he at first supposed belonged to the family of Struthiones. Subsequent examination however has led Professor Owen to the conviction that although witness, these birds have an intimate connection structurally and physiologically with the ostriches as with any other group of recent birds.

From an examination of the various bones thus collected, Professor Owen was enabled to point out that the fragment of bone which he had first received belonged to a species of the genus not only much larger than any of the other species indicated by these remains, but larger than any form of existing bird. To this species he gave the name of Dinornis giganteus, and found that the height of this bird must have been between 6 and 8 feet, while its feet presented a peculiar structure, the four toes on the feet being 4, and the toes of the foot 2 inches. These were described as—D. ingens, attaining a height of 9 feet; D. struthoides, 4 feet; D. dromaioides, 5 feet; D. struthoides, 4 forwards and 8 backwards. In addition to these were described—D. curtus, D. ornatus, D. ocellata, and D. carrus. These remains showed the existence of a number of birds, varying in size from the almost flightless Bustard to birds of the size of the Dodo, the Emu, and the Ostrich, and one larger than all.

On a subsequent examination of the bones of D. ingens and D. dromaioides, Professor Owen discovered a back toe which he had seen nowhere in the other species, and for these he proposed the generic name Polyapteryx. To these two species he added a third species, P. gersonioides, Dr. Mantell gives the following:—A further discovery of the remains of birds in New Zealand:—

"In 1846 and 1847 my eldest son, Mr. Walter Mantell, of Wellington, who had resided several years in the colony,
explored every known locality of these fossil bones within his reach in the North Island, and went into the interior of the country, and located with the natives, for the purpose of collecting specimens, and of ascertaining whether any of these great bones are in existence, resolving, if they appeared to be the least chance of success, to penetrate into the unfrequented regions, and obtain a live Moa. The information gathered from the natives offered no encouragement to follow up the pursuit, but tended to confirm the idea that there was not a specimen in the country. To prove the occurrence of this species, related to the Apteryx, the living diminutive representative of the stupendous ostrich-like birds which once trod the soil of New Zealand. My son succeeded however in forming the most interesting collection of these remains hitherto obtained. It comprised between 700 and 800 bones belonging to birds of various species and genera, and differing considerably in magnitude and age, some belonging to very young individuals, in which the epiphyses of the long bones are distinct from the rest, while others are those of adult and aged birds. The chief part of this collection is now deposited in the British Museum.

The locality from which these specimens were obtained is thus described by Mr. Mantell:—"Near Waikorati, 17 miles south-south-east of the headland of the Point, a level plain, three-quarters of a mile in length and 150 in height; it consists of sandy clay distinctly stratified and traversed by dykes of columnar trap, the columns being at right angles to the sides of the veins. In a little bight, south of Island Point, there is a stretch of sand which forms the mainland at the entrance of the River Waikorati in front of the native Kaiks, named Makuku, is situated the exposed parts of the so-called turbarry deposit, whence bones of Moas and other birds of various kinds have been obtained in number and perfection. This bed is about 3 feet in depth and not more than 100 yards in length, and lies immediately on a stratum of tertiary blue clay; its inland boundary is obscured by vegetation, and appears to be of a very limited extent. The bed is entirely submerged, and only visible when the tide has receded. It consists almost wholly of decayed vegetable matter, and its surface is studded with the undisturbed roots of small trees, which appear to have been burnt to the ground at some remote period. It is a light, sandy, elastic earth, of a blackish-brown colour, and emits a strong fetid odor when first collected; from the large quantity of animal matter it contains I conceived it was originally a swamp or morass, in which the New Zealand Plax (Phorhinum torquatum) still abounds. It is covered by the heath, and it is probable that the water in the bed, for fear that it will be entirely washed away, without yielding to the paleontologist all the desired information respecting the extinct animals whose relics it envelopes; for the natives and whalers are well aware of the interest attached to the bones by Europeans, and they seize them indiscriminately on any specimen exposed by the receding tide, and if it cannot be readily extracted they break it off, and thus many a valuable relic has been destroyed. Their cupidity and avarice have been so increased by the language given by casual visitors, that the cost of specimens has increased to an unreasonable amount."

In their general aspect the bones which have been obtained from this spot closely resemble those obtained from the oseiferous caverns in Germany. Professor Owen gives a detailed analysis of their chemical composition, and from this infers that they may have been recently deposited. Mr. Mantell obtained bones also from North Island:—"On the western angle of the island sixty miles south-west of New Plymouth, there is a stream called Waikorati, into which empties itself into the sea a: about a mile and a half south of Waimate in the Ngiiruga district. Part of the neighbouring country is elevated table-land, with deep tortuous gorges, and the edges of the cliffs near the foot of the mountain take the water into the course of the river. That of Waingaonou, which is as tortuous as any to them, takes its rise in the neighbouring volcanic ridge, and has evidently at a former period discharged itself far distant from its present embouchure, as is proved by the existence of a line of cliffs which extends inland, and has manifestly been produced by the corroding action of the river. Driven from its course probably by a change in the relative level of the land and sea, the stream has formed its present channel, which cuts through a bed of loose conglomerate, 100 feet thick, overlying a deposit of finely-laminated sand, which covers a thick stratum of blue clay full of shells. The conglomerate consists of pebbles and larger boulders of an infinite variety of volcanic rocks; the clay is very fine, but more or less indurated, and well interspersed with marine and resemble species existing in the South Pacific Ocean; but I suspect many will be found specifically distinct from any recent forms. Between the two bluffs near the embouchure of the river, there is a large flat bed of the sandstone, which on my first visit was strewn with bones of men, moas and other birds, and two species of seals. I had some deep openings made near the foot of the ancient cliff on the top of which is the Pa or native village of Ohawato-koloko, and at the same level as the flat on which I had observed the fragments of bones I came to a regular oseiferous deposit. The bones however though perfect were as soft and plastic as putty, so that if grasped strongly they changed as it were by magic into pipeclay; and it was necessary to dig with animals to preserve them to the air and sun to dry, before they could be packed and removed. Unfortunately the natives soon caught sight of my operations, and came down in swarms, men, women, and children, trampling on them and pulling out the bones, leaving them in disorder, setting upon every morsel exposed by the spade. My patience was tried to the utmost, and to avoid blows I was obliged to retreat and leave them in the possession of the field; and to work they went in right earnest, and quickly made away. The bones of other native creatures, D. d'escrignaw, and D. camaronius; also of Palapteryx ingess, variety rubra, and of a new species, P. geranoides. Notwithstanding the great number of bones that have thus been examined, one fragment only of the wings or humerus has been detected. This indicates the rudimentary condition of the bones in these birds. The hammers found Professor Owen regards as belonging to a species of Palapteryx. The following is a summary of the nature of this collection by Professor Owen. 'These bones are only large and particularly referrible to five species of Dinornis, Palapteryx, and Notornis, and there are 18 taro-metatarsals, with the articular surface for a very strong hind toe, and of a conformation more nearly resembling those of the Dodo than of the Dinornis. Because of the great length of these bones, as compared with the size of the tibia, and the articulation of the tarsus, there is a singularly large complete bone canal for the flexor tendons at the back part of the proximal end of the tarso-metatarsal; the perforation above the articular surface of the side between the outer and middle metatarsals for the tendon of the adductor muscle of the arch, and the more extensive groove for the inner toe—all concur to indicate the generic distinction of the bird to which it belonged from either Dinornis or Palapteryx; and I propose to distinguish the new genus by the name of Notornis and the present species A. odidaformis."

"With the remains of bones found upon the banks of the river Waingaonou were mixed the fragments of egg-shells. The eggs to which the fragments belonged were supposed to belong to the ostrich, and the comparison of the egg with the subject the recent discovery of a large egg in Madagascar is interesting."

In a report to the French Académie de Sciences, M. l'abbé Geoffroy St. Hillaire described three enormous fossil eggs
from Madagascar, and some bones belonging to the same bird. The captain of a merchant- vessel trading to Madagascar one observed a native using for a domestic purpose a vase which much resembled an egg, and upon examina- tion proved to be one. The native stated that such eggs were to be found in the interior of the island, and eventually procured the eggs and bones exhibited by M. St. Hillaire. The larger of these eggs is equal in bulk to 136 hen's eggs, and hold two gallons of water. M. St. Hillaire pro- poses the name of Epicorax for the monster biped of which these marvellous eggs and bones are the first evidence brought under the notice of naturalists. Casts of these eggs have been made. Amongst the bones sent home by Mr. Mantell, the remains of a new genus, Notornis, were found. It belongs to the same family as the Brachypteryx and the Rallidae, and the interest that attaches to it in this relation is the fact that Mr. Mantell succeeded in obtaining a single living specimen. Many persons had reported the existence of a wingless bird as large as a fowl, and with red head and legs, with a cry sounding like 'Keo Keo.' The following is Dr. Mantell's account of the discovery and the method of obtaining it; "On my son's second visit to the southern part of the Middle Island (as Government Commissioner for the settlement of native claims), he fell in with some seamen who had been pursuing their avoca- tions along the little frequented islets and gullies of Drury Bay, when they mentioned seeing a bird not unlike the one described in the skin of a recent specimen of Notornis Mantellii. It appeared that when frequenting the coasts in search of seals and other game, these men observed on the snow, with which the ground was then thickly covered, the foot-tracks of a large bird, or rather an estate, the latter at a considerable distance, they caught sight of the object of their search, which ran with great speed and for a long while distanced their dogs, but was at length driven up a gully in Resolution Sound, and captured alive. It nipped, bit, and fought and struggled violently; it was kept alive three or four days on board the schooner and then killed, and the body roasted and eaten by the crew, each partaking of the dainty, which was said to be delicious. The skin, with the foot-tracks and the bones, I have fortunately obtained by my son while in good condition, and thus perhaps the last of the race of Moho was preserved for the naturalists of Europe. Upon comparing the head of the bird with the fossil crania and mandibles, my son was at once convinced of the specific identity of the recent and fossil specimens; and so delighted was he by the discovery of a living example of one of the supposed extinct contemporaries of the Moa, that he wrote to me and stated that the skull and beak were alike in both, and that the abbreviated and feeble bones corresponded with the fossil; and that they were in perfect accordance with the indications afforded by the humerus and sterno found by him at Waingougoa and now in the British Museum, as pointed out in the Zoological Transactions. In this year, my son having, on a voyage in the Whales, my son visited on his homeward route to Wellington, the Notornis was a perfect novelty, and excited great inter- est. No one had seen such a bird, but all agreed that it was the traditional Moho or Takahé, which they had believed was utterly extinct."

"This beautiful bird is about two feet high, and much resembles in its general form the Porphyrio melanocephalus, but it is larger and stouter, and generally distinct; the characters predicated by Professor Owen from the fossil remains being clearly observable. It has a white crown and a black and white neck, and strong, and as well the legs were of a bright scarlet in the living animal. The neck and body are of a dark purple colour, the wings and back being shot with green and gold. The wings are short and rounded, and remarkably feebly both in structure and plumage. The tail is scanty, and white be-neath. The specific identity of the recent and fossil Notor- nis is confirmed by Mr. Gould, who has published a coloured figure the size of the original in a supplementary number of his Journal of Natural History. In addition to the bones of the animals mentioned, remains of other birds were found in the Mantellian collection. These were of a species of nocturnal Parrot, belonging to the genus Necro, of a probably extinct species of Apteryx, of a peculiar order of Diomedes chlororhynchos, and also of the Penguin."

For the structure of the Apteryx and its relations to other birds, see the article STRUTHIONIDAE.

In 1861 Professor Owen received from Governor Grey a large collection of specimens from New Zealand of the bones, and more especially the skulls, of several of the spe- cies, which he described in a fifth memoir presented to the Zoological Society. An almost perfectly restored skeleton of the Dinornis giganteus exists in the Museum of the Col- lege of Surgeons. Professor Owen concludes one of the memoirs referred to with the following general remarks:— "The extinct Aves may be divided into two classes, one the van- 1041 bed of some of the species peculiar to New Zealand, and which have finally become extinct in that small tract of dry land, suggest it to be the remnant of a larger tract or contin- uent over which this singular Struthionida Panna formerly ranged. One might almost be disposed to regard New Zea- land as one end of the mighty wave of the unstable and ever-shifting crust of the earth, of which the opposite end, after having been long submerged, has again risen with its accumulated deposits in North America, showing us in the Connecticut Sandstones of the Permian period the foot-prints of the gigantic birds which trod its surface before it sank; and to surmise that the intermediate body of the land-wave along which the Dinornis may have travelled to New Zea- land has progressively subsided, and now lies beneath the Pacific Ocean."
When we determine and (which DIV treasures)

Authors', originally his life attained, researches Leila, originally productions some time, the 18th century, reached a second edition. But though he had much poetic taste, he was not fitted to be a poet or creative writer; and he was not long in finding out that his true destiny was to give to his country a series of works illustrative of historical and political history. The journeys he worked to prosecute researches in literary history and gossip. It was in the year 1790 that he published anonymously a little volume entitled 'Curiosities of Literature.' The success of this volume determined him to prosecute the work which he had there undertaken. Accordingly, with the exception of the volume of romance above alluded to, and we believe, one other anonymous publication, all Mr. D'Israeli's further productions during his long life consisted of the fruits of his labours. Some of the researches before mentioned were prosecuted partly in the British Museum, where he was a constant visitor at a time when the readers who had access to its treasures were not more than half-a-dozen daily; partly in his own library, which, especially in the end of his life (when he resided on his own manor of Bradenham in Buckinghamshire) was very extensive. The results of these researches were put forth from time to time either as additions to his 'Curiosities of Literature' (which thus eventually amounted to seven volumes) or in the separate publications of six volumes; or as independent publications. Among the independent publications may be mentioned his 'Essay on the Literary Character' originally published in 1790; his 'Quarrels of Authors, or Memoirs of Literary Controversy,' and his 'Intrigue into the Literary and Political Character of James the First.'—works originally published between 1812 and 1822, and since then published collectively under the title of 'Miscellanies of Literature,' and his 'Life and Reign of Charles the First,' published in five volumes in intervals between 1828 and 1831.

In acknowledgment of this last work he was made D.C.L. by the University of Oxford. He contemplated a 'Life of Princess Maria' also a 'History of the English Free-thinkers,' and had made notes for both as far as the optic nerve which attacked him in 1839 prevented him from executing either. With the assistance of his daughter he selected from his manuscripts three volumes, which were published in 1841 under the title of 'Amemities of Literature.' His last years were spent in revising and re-editing his former works, and he died in 1848 at the age of 82. "He was," says his son, from whose memoir, prefixed to a new and posthumous edition of his 'Curiosities of Literature,' where the following extracts are quoted, "an eminently delightful literary character, a man who really passed his life in his library. Even marriage produced no change in these habits: he rose to enter the chamber where he lived alone with his books, and at his chair lamp was ever lit within the same walls." He was born July 8, 1769, and he had been become rather corpulent.
for dissolution of marriage, he may at the same time claim damages from the adulterer, who must be made a respondent. The damages are ascertained by the verdict of a jury, the old action of crimen con, being abolished by the statute. The adulterer may also be condemned in the costs of the whole proceeding.

After the date of dissolution has been duly pronounced, either party is at liberty to contract a new marriage. Out of respect, however, to the religious scruples of a part of the community, clergyman of the established church are not compelled to solemnize marriages of persons who have been pronounced guilty of fornication. In case of a general refusal on the part of the clergy to celebrate marriages under such circumstances, parties so situated may of course marry with the other formalities by which that class of works are performed, and have them registered and held to be a refusal. By this combination of qualities he amassed a quantity of materials which nobody before him had ever supposed to exist, and he made such good use of them that a new work of the same nature, and his most important reference to Dobrentei's 'Nyevelűműfek,' which has become one of the principal monuments of Hungarian literature. How the revolution of 1848 affected him we have not seen stated, but it is well known that his friend and fellow-promoter of progress, Conni Stephan Steczeny, became a maniac, Dobrentei was still engaged in collecting materials for his great work when surprised by death on the 27th of March 1851, at the age of 66. He was the author of numerous lives of Hungarian worthies, both in the periodicals to which he contributed, and in the book 'New Hungarian Histories,' the first volume of which, a quarto volume, was published at Buda in 1835, and the fifth was in progress at the time of Dobrentei's death. His labours on this work were an outlet for the delight of his life, he pursued them with irrepresible ardour, and on the result his reputation rests securely. When he began, hardly anything was known of the history of the Magyar language for a thousand years; he, in his darkness he left enriched with light. He was indefatigable in discovering the existence of old correspondence or documents in family archives; when he had once discovered them, he was no less eager in obtaining permission to copy and make notes of them, and he never made a refusal.

DOBRENTZ, GABOR or GABRIEL, an Hungarian author and antiquary of distinguished merit, was born at Nagy-Szécsény, in the county of Vaspré, in 1768. He showed himself very early not only a remarkable zeal for the Hungarian language and literature, but a singular natural inclining for others in his views. At Osdenburg, a town not far within the frontier from Austria, and chiefly inhabited by Germans, he succeeded in getting up an Hungarian literary society, of which he became the secretary; and under his superintendence, which he discharged with industry and attention, it was published. At twenty he studied at Wittenberg and Leipzig, and in 1807 was recommended by Kázmery, then the almost acknowledged head of Hungarian literature, to the post of tutor to Count Louis Gyulai, a noble gentleman who, for years, had resided in a resident in that country. With the literary contributions of some of his Hungarian and Transylvanian friends, and the pecuniary contributions of the Transylvanian magnates, he set foot and edited a magazine, which was issued at Kázmery and the remaining nine at Pesth, after which it ceased for want of support; but it contained so many articles of interest that no Hungarian library is considered complete without it. In 1820 Dobrentei removed to Pesth (then, or rather, that of Hungarian capital, as he lived, in the occupation of several highly respectable official posts of a legal character, and in such constant literary activity that he became the acquaintance or friend of almost every person of any note connected with Hungarian literature. Indeed, almost all the information that has been put in circulation on that subject in England had its origin in Dobrentei. He was the friend and correspondent of Dr. now Sir John Bowring, to whom he supplied much of the information for his 'Progress,' and he also contributed to Miss Pardoe materials for her account of Hungarian literature and authors in her 'City of the Magyars,' and he wrote the article on the subject in the 'Leipsic Conversations-Lexikon,' which, by its being translated in Lieder's 'Encyclopedia,' and the Glasgow 'Popular Encyclopedia,' has become familiar to thousands of English readers. As a poetical writer, Dobrentei was not successful; his original poems appear to have been pleasing, and no more; and though his translation of Shakspere's 'Macbeth' was acted at Pesth in 1825, it did not receive such a welcome as to encourage the publication of his versions of the other masterpieces of Shakspere, which were reserved in Hungarian for the more successful pen of a lady, Emily Lecompton, who, in the time of the Academy, is the only translator of our great poet in any language. Dobrentei was more at home in his exertions to establish a 'Casino' at Pesth, an establishment of nearly the same kind as an English club of our own days, but borrowed both in plan and name from Italy, where it is made use of not only for the amusement of the society of the capital, but to enliven the dullness of the provincial towns. He was, after Conni Stephen Steczeny, the most influencial person in promoting this institution, and was for some years its secretary, but relinquished his post after three years' service, in the year 1831, of which he was also a zealous promoter. Kohl, the traveller, bears testimony to the extraordinary influence of these establishments on the whole tone of the Hungarian villages, where they have been imitated on a small scale. In 1837 Dobrentei received an intimation from the government that his holding the post of secretary to the Academy any longer would be incompatible with his official duties, and he then devoted himself to the editorship of his great work, the 'Rgvi Magyar Nyevelűműfek,' or 'Ancient Monuments of the Magyar Language,' the first
at Bergamo, in Northern Italy. He studied in the Lyceum of that town, and his father having originally destined him for the law, it was somewhat late before he commenced his musical studies. In 1827 he returned to his native town, and took the direction of the Musical Institute of Bergamo, of which Simone Mayer was then director. Here he remained three years, and in 1816 moved to Bologna, where his musical education was completed. He subsequently travelled with Mattielli, and on dispute with his father, entered into the army, and while in garrison with his regiment at Venice in 1818 produced his first opera, 'Ente di Borgo.' He continued to write for the theatre, and in 1822 left the army. His earliest pieces were not successful, and had been performed, and not till 1850, when he produced 'Anna Bolena' at Milan, that he began to take rank with the higher class of musical composers. In the course of these first twelve years of his career he composed twenty operas in all. On the fiftieth years from 1830 to 1844, when his last opera, 'Catarina Comnoro,' was performed, he produced 33 operas, of which several have sunk into oblivion, but others still retain their places on the stages of Italy, Germany, France, and England. Some are especial favourites, and frequently performed. Among these are the most fortunate productions may be mentioned 'Anna Bolena,' Milan, 1850; 'L'Elisa d'Amore,' Milan, 1832; 'Lucrèzia Borgia,' Milan, 1833; 'Marino Faliero,' Paris, 1838; 'Lucia di Samogna,' Naples, 1855; 'Le Prophètes,' Paris, 1841; 'La Fille Du Régiment,' Paris, 1840; 'La Joliesse,' Paris, 1840; 'Linda di Chamonix,' Vienna, 1842; 'Don Pasquale,' Paris, 1843; 'Maria di Rohan,' Vienna, 1843. Most of these later operas, besides his usual grace and facility, exhibit a strong tendency in the management of the moat and skill in instrumentation, much superior to his earlier productions. His artistic powers were thus manifestly improving and expanding towards the termination of his musical career. Soon after the performance of his 'Lucia,' which excited universal admiration, he was appointed Professor of Counterpoint in the Royal College of Music at Naples, and after the production of 'Linda' at Vienna, he was named chapel-master and composer to the imperial court. In 1845, while attending to the duties of mental and physical habits of intermission, began to show themselves, and he was for some time in a insanitary asylum. In October 1847 he was removed to his native town of Bergamo, where he died on the 8th of April 1848. (Nouvelles Biographies Générale.)

DONOSO CORTES, JUAN, an eminent Spanish statesman and author, was born in 1809, of wealthy parents, at the town of El Valle in Extremadura. He was so precocious that at the age of eleven he studied logic at Salamanca, and had commanded a host of political career before he was of age to enter on a legal one. A pamphlet however which he composed under the title of a 'Memoir on the Rights of Isabel the Second,' was suppressed by the advice of his friends as containing ideas so ultra-liberal as to be certain to offend. He was appointed in the same year to a post in the ministry of Grace and Justice, and in the next published his 'Considerations on Diplomacy and its Influence on the Political and Social State of Europe, from the time of the Revolution of July to that of the Quadruple Alliance.' In 1835 he was sent as a royal commissioner with General Rodil to bring back obedience to his native province of Extremadura, and acted with such success as to receive the grand cross of the Order of Charles III. He held a high official station; but dissatisfied with the turn that affairs had taken, he resigned his post, and for some time occupied himself in combating the party which supported the revolution of La Granja. He founded the newspaper 'El Piloto,' in which he was assisted by Alcalá Galvez, the great favourite of Queen Christina. In the 'Annuaire de Madrid,' a review or rather magazine established on the plan of the French 'Revue des Deux Mondes,' his first article was in which one of a series on 'Spain since 1833.' He delivered in 1837 at the Athenaeum of Madrid, a series of lectures on the influence of political principles on the arts. He was in France in 1840 at the time of the expulsion of Queen Christina, hastened to offer her his services on her arrival in that country, and is said to have been the author of the manifesto which she issued from Madrid to the Emperor of Spain. He returned to Madrid on a commission from her to defend her rights against Espartero, but his efforts were unsuccessful. He then returned to France and occupied himself with the composition of a 'History of the Minority of Queen Isabel II.,' passages of which were published in the 'Athenaeum' of Madrid in 1843. He subsequently returned to Spain. He was ambassador to Prussia at the time of the revolution in 1848, and afterwards ambassador to France, a country for which he always avowed a strong partiality. It was while holding that post, an ambassador extraordinary of Spain, that he married the marriage of Louis Napoleon with a Spanish consort, that he was seized with an attack of pericarditis, which carried him off, after about a month's illness, in the 3rd of May 1853, at Paris.

A. H. Downham. From his own criticisms and writings, 'Coleccion Elogica de los Escritos de Excentismos Señor Don Juan Donoso Cortes,' was published in two volumes at Madrid in 1848. It comprises none of his poetry but most of his political writings that we have mentioned, and several of his articles from the reviews, which seem to indicate those of the classical and Spanish taste. There is much that is as questionable on most of the subject on which he touchtes.

DOON. [AULDEN.] Institute of Agriculture, [Oxfordshire.] DORNDOH. [SUTHERLAND.] DOUBLEDAY, EDWARD, a naturalist of eminence, was born in 1810, and died in London in 1849. The family of Doubleday are honorably distinguished for their devotion to natural history. Edward Doubleday was the son of a musician and the elder brother of frontispiece. On his return from America he was appointed one of the curators of the British Museum. Large collections in this institution afforded him abundant materials for increasing his knowledge and developing his views of the structure of insects. The results he made known in a variety of papers, but more especially in his work 'On the Genera of Diurnal Lepidoptera.' This work, which was published in parts and left unfinished at the author's death, consisted of descriptions, with coloured figures, of great beauty and accuracy, of all the genera of butterflies. This family of insects was studied by Mr. Doubleday with the greatest industry, and his contributions to our knowledge of their forms are the most valuable of his labors. He devoted also considerable attention in publishing a work on this subject. He also contributed a paper 'On the Occurrence of Alligators in East Florida,' to the 'Zoologist.' A list of his papers will be found in the 'Aldine' volume of Agassiz's, 'Bibliographia Zoologica,' published by the Ray Society.

DOWNHAM. [NORFOLK.]
DRACONINA, a sub-family of Scansions belonging to the family Agamidae, the tribe Strobilosaur: and the sub-order Pachyglisora of Dr. J. E. Gray's arrangement. The family of Agama, or Agamidae, is thus defined by Dr. Gray—

"Teeth implanted on the end of the jaws. Tongue short, depressed, apex entire or slightly nicked. Eyelids convivnt, valvar. Feet, for walking. Toes all free, unequal; the thumb of the hind feet on the same plane as the other toes; the little toes lower down on the ankle than the thumb. The thumb is anterior and internal, and the great toe of the hind feet occupies the same position, the thigh and foot being bent forwards. This is proved by analogy, this toe being the only that is clawless in the Gekko, which have the clawless thumb, and in Ameis, where the thumb and great toes are simple, and not dilated beneath, like the other toes."

The synopsis of the genera of this family, according to the 'British Museum Catalogue,' is as follows:—

I. Body compressed. Living on trees.
      a. Ribs elongated, exerted, supporting wing-like lateral expansions. Throat with 3 pouches.
      1. Draco.—Ears naked. Nostril below the face-ridge.
      2. Dracoella.—Nostril above the face-ridge.
      3. Dracocei.—Ears covered with scales.
         b. Toe 4 or 5. Ears exposed.
   b. Sitana.—Males with an elongated porch. Females without any porch. Toe 5-5. Tail with elongated keeled scales beneath. Scales of back small, often with scattered larger ones.
      + Ears hidden under the skin.
      ↑↑ Ears exposed.
   10. Tarsia.—Scales of the belly keeled, of the back unequal. Eyebrows and parotids unarmed.
   11. Anomolepis.—Scales of the belly smooth, of the back equal. Eyebrows and parotids armed.
      *** Toe 5-5. Tail with broad rhombic keeled scales beneath. Scales of back uniform.
      *** Toe 5-5. Tail with truncated keeled scales beneath. Scales small, keeled, in cross rings.
   15. Callosoma.—Parotids swollen, armless. Throat lax. The nape and back with a low crest. Tail rather compressed. Face-ridge rounded, with small scales.
   16. Charassia.—Parotids swollen, with some spines above.
      The nape and back with a low crest. Tail tapering. Face-ridge distinct, with enlarged imbricated scales.
   17. Gindalia.—Parotids rather swollen, with 2 or 3 spines above. Nape and back not created. Tail tapering, round. Face-ridge indistinct.

B. Femoral pores distinct.
   18. Loparia.—Back and tail with a fin-like crest, supported by bony rays. Head squarish.
   19. Phrynomalus.—Back and tail with a crest of compressed scales. Head swollen behind.

   a. Neck with a frill-like expansion on each side.
   20. Chlamydosora.—Head rhombic.
      ** Neck simple.
   25. Gramnatophora.—Back not crested, with cross rows of larger scales. Femoral pores numerous.

      * Pre-anal and abdominal pores in several rows.
   27. Stellos.—Tail with rings of large spinose scales. Parotids spinose.
      ** Pre-anal pores in a single line. Abdomen poreless.
   29. Trapelus.—Parotids unarmed. Scales minute. [Agama]
   b. Pre-anal and femoral pores none.
      * Ears exposed. Body and limbs with large spinose tubercles.
   30. Moloch.—Neck with a convex tubercle above.
   32. Megalochila.—Angle of mouth fringed. Toes fringed on the sides.
   33. Uromastyx.—Tail broad, depressed, with complete rings of spinose scales.
   34. Saura.—Tail broad, depressed, with scales of the upper part of the rings spinose; of lower, armless.
   35. Leiolopia.—Tail round, elongate, tapering, with whorls of smooth scales.

The genera and species of the family Draconina are as follows:

1. Draco.—Head small. Nostril in a scale, rather tubular on the side of the face-ridge. Tympanum deep, but the ear visible, opaque, white. They live on trees, walking with agility with their wings folded on their sides, but they expand them and use them as a parachute when they throw themselves from the tops of trees. They spread out their pouches as they lie on the trunks of the trees. Scales unequal, some larger, keeled. Nape created. For skeleton of Draco, see Dragam.
   a. Coliana, Linn., the Flying Lizard. It is the D. major of Lamarck, D. Halli in Dana, D. Bourdinneria of Lesson, and the D. Daudini of Dumfri. The scales of the back are rather broad, generally smooth; of the throat granular, of the same size; the lateral pouches of the males moderate, rounded at the end, covered with oval keeled scales: the throat black-spotted; wings gray, fulvous, or brown, spotted and marked with black, sometimes forming four or five oblique black bands near the outer edge; the sides with a series of large broad keeled scales.
   b. Eunectes, the Timor Flying Lizard. It is the D. exicrce Timorinserter of Schlegel. It has flat scales, rather large, smooth, unequal, with a row of rather keeled scales upon and on each side of the vertebral line; wings reddish, brown-spotted; lateral pouches (of male) moderate, rounded at the end, covered with large keeled scales; sides with an interrupted series of large keeled scales.
   c. Drimobius, Kuhl, the Fringed Flying Lizard. Scales of the back small, equal, mostly smooth; the throat with many circular spaces, covered with large granular scales; head...
white, brown-netted; lateral pouches of male elongate, angular, setae, covered with large keeled scales; wings with short whitish longitudinal lines; sides with a series of small triangular keeled scales, placed in groups of two or three; nostrils sub-superior. For figure of Draco fimbrinata, see D Tipo.

2. Dracocela.—Head small, covered with small unequal scales; the nostril roundish, in a scale, erect, vertical on the face-ridge; tympanum exposed, and opaque.

* Nape crested.

D. Dusunieri, Dusunier's Dragon, has moderate scales, rather rhombic; the sides with a series of rather larger scales, placed in roundish, small groups; with a small boy point at back and front angle; wings with large brown spots near the body, and largely marbled near the outer edge; a black band across the throat; base of the ponch blue-black; the limbs moderate.

** Nape not crested.

D. Narcrastopen, the Red-Throated Dragon. The orbit with a small bony point above, upon the front and back edge; scales of the back equal, smooth, the sides with a series of keeled scales; nape not crested; a large round black spot on each side of the base of the position; wings brown-netted, without an elongate.

3. Dracocactus.—Head quadrangular, covered with small unequal scales; nostrils lateral, on the face-ridge; tympanum hid under the skin, covered with scales. Weigmann described this species as having but five exserted ribs, but the specimens in the British Museum, like the other dragons, have six on each side.

* Nape not crested, with a longitudinal fold.

D. quinquedactilus, the Banded Flying-Lizard. Wings with five cross bands; scales of the back keeled; nape with a longitudinal fold, not crested; nostrils superior, erect; ears covered with small equal granular scales.

** Nape not crested. Ears slightly concave.

D. lineatus, the Lined Flying-Lizard. Head gray, white-spotted; wings dark-banded, with small white longitudinal lines; the sides and throat bluish-black, with large white spots; the ears indistinctly marked, covered with three flat scales; base of the tail rounder above, with a slight crest on each side.

D. ornatus, the Banded-Head Dragon. Gray; head black, cross-banded; chin black, dotted; wings gray, reticulated with black, and with broad black bands at the edge; scales rhombic, of the middle of the back larger, keeled; of the sides smaller, smooth; ears covered with small equal granular scales; tail slender, compressed, with five keels above and two stronger keels beneath, rather depreased at the base, with five small eyes.

D. maculatus, the Spotted-Winged Dragon. Gray; black-spotted; wings black-spotted; throat gray; pouch of the male elongate; scales of the back rather unequal, rhombic, keeled, of the sides rather smaller; sides with a series of large keeled scales; ears rather sunk, with unequal flat and scales; tail slender, with a central keel above and five more small ones on the sides; base dilated, with five nearly equidistant keels above.

D. ephippinum, Weigmann's Flying-Lizard. Wings reddish near the body, with large brown spots, yellow near the edge; throat yellow, black-spotted. This may be the same as the former species, but the wings are subelliptic, and the scales do not exactly agree.

D. D. [CALLIOPE.]

DRAKEA, a genus of plants belonging to the natural order Orchidaceae. D. elastica has a single flower placed at the end of a slender smooth shoot from 15 to 16 inches long, and its labellum, which is hammer-headed and black, is long and narrow, on a long arm with a moveable elbow-joint in the middle, is stated by Mr. Drummond to resemble an insect suspended in the air and moving with every breeze.

DRAKE. [Minn.,]

DROF. [DRAKE.] DROZ, FRANCOIS-XAVIER-JOSEPH, was born at Beasopon on the 31st of October, 1773. Having visited Paris for a few months in 1792 he witnessed the massacre of September 17, after which he returned to Germany, and enlisted as a volunteer during the national enrolments. His comrades, according to the fashion of the times, elected him as their captain. But after a short service of little better than three years, he quitted the army for ever in 1796, and devoted the rest of his life to study. About the same time he obtained by his family influence the appointment of Professor of Belles Lettres to a public school in his native town; and in 1799 he published his 'Essai sur l'Art Graphique.

In 1802 his school having been suppressed, he went to Paris, where he settled definitively, and became connected with Villemin, Cabanis, and all the leading litterati of the time. By the advice of Cabanis, he published his 'Idees,' a work of fiction in 1804, to attract attention to his profession. In 1806 he published his 'Essai sur l'Art d'Etre Heureux,' which was followed by an 'Eloge de M. de Maistre,' in 1811, for which a medal was awarded to him. From 1816 to 1830 he wrote for several newspapers, inculcating the views of his system, and the principles of moral education from politics. He then joined Picard in writing his 'Memoire de Jacques Favel,' a name imitation of the then fashionable; he wrote under the name of 'De la Philosophie des Systèmes.' The same year as 1806 he was elected a member of the French Academy.

He had long desired to hold a professorship, and at length in 1832 he was appointed to lecture, by authority, at the medical college, where he had previously lectured. In 1839 he published his best work, 'L'Histoire du Règne de Louis XVI.' His gentle and unambitious life came to a close on the 6th of November, 1850, when he died as peaceably as he had lived.

Although his works are written in a very unpretending style, they are written from the heart, and it is probable that all the principal critics of his country have mentioned them with esteem.

DUC-K.-WREED. [LUMDA.]

DUGPINEOYSIS, a mineral, consisting of an arsenate and sulphuret of lead. It occurs in cedrelahedram of a dark steel-gray colour in the Dolomite of St. Gothard. The specific gravity is 4.55.

DULWICH COLLEGE. Under ALLANY, WILLIAM, in the 'Penny Cyclopedia,' vol. I., p. 347, an account was given of the college of his institution. As the value of the property with which he had endowed it had enormously increased, it had been long felt that the income was no longer employed in accordance with the donor's intentions, and an Act was therefore passed, 20 & 21 Vict. c. 64, for its better management.

According to this Act, the educational branch of the college is very largely extended; two schools are established, an upper and a lower school, in which the classical and modern languages, mathematics, and natural sciences, are taught. The school of mathematics, physics, chemistry, civil engineering, and other departments of knowledge are to be taught to daily scholars, on the payment of a small fee, with no limit to the number except the amount of funds. The school of natural sciences is made more accessible by the number of boys, to be elected by competition (at present not to exceed twenty-four, but to be increased when there are sufficient funds), are to be foundation scholars, to be provided with board and lodgings free; and there are eight exhibitions in the upper school for boys of the upper school, tenable for five years while studying an English university or for a profession; and twelve of 40L. for boys of the lower school, tenable for four years for the like purposes.

The life interests of the present master, warden, fellows, and poor brothers and sisters are provided for; but for the future management nineteen governors are to be chosen; namely, two each to be elected by the four parishes of St. Saviour's, St. George's, St. John's, and St. Mary's, respectively; two of the same parishes, respectively; two of the parishes of St. James's, Middlesex; and St. Botolph, Bishopsgate, to hold office for seven years; and the remaining eleven to be appointed by the Court of Chancery, without any other restriction than that one must be resident in Dulwich. There is to be an upper and a lower master of the upper school, a tutor of the upper school, and a school chaplain, and an organ for the chapel, which is to be maintained as a place of worship for Dulwich. The net income of the college is to be divided into four equal parts: three to be devoted to the education of the poor, and the remaining fourth to the support of aged men and women, and present (1858) not to exceed twenty-four, and to be chosen in equal proportions from the four parishes above named.

Provision is also made for the maintenance and presentation of these school scholarships; but the income arising from this fund, it is to be applied in providing instruction in drawing and designing for such of the boys in the two schools as evince an inclination and capability for their acquisition.
DUM-B-CANE. [Cabarau, S.1.] DUMBLENE. [Prestgibourne.]

DUNDAS. [Canada, S.2.]

DUNMANWAY, Cork, Ireland, a market-town and the seat of a Poor-Law Union, is beautifully situated on the river Bann, near its bend, to the west of the town of Banbridge, 23 miles S.W. from Cork, 190 miles S.W. from Dublin. The population in 1851 was 2222. Dunmanway Poor-Law Union comprises 15 electoral divisions, with an area of 373 square miles, and a population in 1851 of 17,917.

The town is situated on level ground almost entirely surrounded by lofty and rugged hills. The greater part of the town was built by Sir Richard Fox, who also obtained for it a charter as a market-town. There are two churches for Episcopalians, viz., an old one, and an octagonal chapel, and a district Bridewell. A Charter school was endowed by Sir Richard Fox. The market is held weekly; fairs are held in May, July, September, and October.

DU NSE. [Benwickshire.]

DU PERRE, VICTOR GUY, a baron of the empire and a French naval officer, was born at La Rochelle on the 20th of February, 1775. He commenced his maritime career in the merchant navy, and entered the French service as a midshipman. He afterwards returned to France after a voyage of eighteen months; and on his having broken out, he entered the republican service in 1795. During the next ten years he took part in many single-ship fights with the English, until he was promoted to the staff on board the Veteran, commanded by Th. D. D'Arbois. In the month of September, 1806, he became captain, and took the command of the Sirène frigate. In March, 1808, whilst off the coast of Bretagne, in company with the Italiensch, Duperre was chased by two ships and three frigates, and whilst making for the port of Bayona, was taken possession of by the enemy. He was detained for an hour and twenty minutes an unequal combat with two of the enemy's ships, keeping up a constant fire from one to the other. Though repeatedly summoned to surrender, he contrived to bring off his frigate; and it is related that at this time it was suggested to the Emperor Napoleon, who had been his patron, to appoint him as the rank of ship captain. He performed several brilliant exploits in the Indian Ocean in 1808 and 1809, after which he became a baron of the empire and consul-general. An August 20, 1810. In December, 1812, he was appointed to command the French squadron lying before Cadiz, and contributed to the capture of that city. In 1816 he became commander in chief of the combined fleet in the Antilles.

DU PERRE was summoned to Paris in February by the government of Charles X. to be consulted respecting the meditated expedition against Algiers. In his reply, Duperre represented the undertaking as extremely perilous and uncertain. It was in spite of his representations that it was resolved upon, and he was then dismissed to the council of the minister, who had refused to confide to him. This fleet set sail on the 20th of May, 1830. It consisted of 103 ships of war, and 257 vessels belonging to the merchant service, and other craft, the whole having on board from 30,000 to 40,000 men. After encountering many difficulties from the nature of the coast and contrary winds, Duperre appeared before the batteries of Algiers on the morning of the 13th of June. The signal share taken by Duperre in the siege and capture of this formidable fort, included Charles X. to raise the siege, July 14th, 1830, a few days before his own fall. This appointment was revoked by the government of July; but on the 13th of August, 1830, the same government made him an admiral, and restored his pension. He became minister of the naval department, and acted as minister of commerce, and was afterwards reappointed to the same office under different administrations. He resigned this office on account of declining health, February 7, 1843, and died November 8, 1846.

DUTCHEM, WILHELM LOUIS, a naturalized American, was born in Neubourg, department I'Eure, on the 27th of February 1767. He was an advocate, practising in Namur, when the revolution began in 1789. In 1793 he is said to have been elected a deputy to the new chamber. During the governments of Louis XVI. and Napoleon, he was allowed to spend his time as he pleased, but without the peremptory demand of his society he had at first adopted of constitutional reform, and on more than one critical occasion took the lead of the liberal party.

After the revolution of July 1830, Dupont de l'Eure became a commissioner of the law in the provisional government, in his own department, and soon after, yielding to the entreaties of Lafitte, he accepted the office of Minister of Justice; but his principles and want of flexibility were suited neither to the government nor to his colleagues, so that he resigned his portfolio on the 27th of December, 1830, and resumed his place in the ranks of the opposition. After the fall of Louis Philippe in February 1848, Dupont de l'Eure became, against his own wish, a member of the provisional government. He wasoral minister in the Jacobin ministry, but by no means a violent republican, he was generally respected as a consistent and honest politician.

DUTENS, JOSEPH-MICHEL, the son of Michel-D'Arc, a French botanist, who was born at Bordeaux on the 21st of May, 1749. His early education was entered when eighteen at the Ecole des Poes et Chausseurs, and at twenty-two years of age he left it with the brevet of engineer. In 1800 he printed his first work at Evreux. "Des Moyens de naturaliser l'Instruction et la Doctrine," and in the same year published a topographical description of the arrondissement of Louviers, in the department of Eure. In 1804 he gave to the world his first work on political economy, an analytical exposition of its fundamental principles. In 1819 he was commissioned by the government to travel in England and France to examine the canal system there, and he extended his labours to all the great commercial works of the country, the results of which were published at Paris in 1819 in "Memoirs on the Public Works of England and France." This work is divided into two parts; the first is devoted to engineering, describing the canals, the works of art employed in their construction, the cost of making, the expense of maintaining, and the system of working; the second is principally to develop the mode of working in England and France. A third part of what should be the principal branches, and discussing the financial condition which would ensure its success. In 1835 Dutens published his greatest work, the 'Philosophy of Political Economy;, or a new Exposition of the Principles of Social Science, which was an expansion with considerable modifications of his previous work, and occasioned much opposition from the economists of the school of Adam Smith. Blanqui says, "It is only a new edition of the doctrines of Quesnas; but with less of advancement in respect to different points;" a criticism occasioned M. Dutens to publish in 1837 a defends of his work, and a second in 1839; and the contest was still going on when the Académie des Sciences elected him a member of their body. He then published his 'Essai comparatif sur la formation et la distribution du Revenu de la France en 1815 et 1836,' a work which contains the best statistical account of the productive riches of France, and has received and deserves high praise. In his last issued work, 'Des pretendues erreurs dans lesquelles, un jugement des modernes économistes, renfou les anciens économistes relativement au principe de la richesse nationale,' in which he defends the theory of Quesnas, Turgot, and their followers, that manufactures and commerce do not contribute to the wealth of a country, is said to have been written after the revolution of 1848. (Nouvelle Biographie Générale.)

DUTROCHET, BERNARD THIERY-HENRI, a distinguished French botanist and natural philosopher. He was born at the Château de Néot, Poitou, on the 14th of November 1776, and died at Paris on the 4th of February 1847. He was the son of a military officer, who emigrated, and his father died in a state of destitution. Dutrochet entered in 1797 entered as a private the military marine, but afterwards deserted. In 1802 he commenced at Paris the study of medicine. He made a brilliant career as a student, was awarded the prize of the Faculty of Medicine in 1806, and was appointed physician to Joseph Bonaparte, king of Spain. He afterwards practised at Bordeaux, and was appointed physician to Joseph Bonaparte, king of Spain. He became principal physician to the Hospital of Burgos, which was then devastated with typhus. He displayed here great energy and
abill. In 1809 he returned to France, and gave himself up to the study of natural science, for which his education fitted him. The tendency of Dufrocq's mind was to develop the laws which regulated the existence of organic beings, and many of his researches have had a permanent influence on the development of the departments of science to which they relate. His name is best known to physiologists from his researches on the passages of fluids through animal and vegetable membranes. The laws which he observed to regulate these phenomena he applied to the explanation of the functions of absorption and excretion in the animal and vegetable body. The passage of a fluid from without inwards he called 'endosmosis,' and the passage from within outwards 'exosmosis.' His views on this subject were published in a work which appeared both in London and Paris in 1828, with the title 'Nouvelles recherches sur l'Endosmosis et l'Exosmosis,' suivies de l'application experimentale de ces actions physiques à la solution du probleme de l'irritabilite vegetale et à la determination de la cause de l'ascension des lieges, de la descente des racines.' The phenomena comprehended under the terms endosmosis and exosmosis were rightly described by Dufrocq, but he was hasty in tracing their cause to electricity, and failed to see that they were parts of a much more general set of phenomena than he had described. His other papers are very numerous, and were on medical subjects not immediately related. Thus we find his inquiries embraced amongst other things the following subjects: a New Theory of Voice; a New Theory of Harmony; on the Family of Wheel-Animalcules; History of the Egg of the Bird; on the Envelopes of the Fossils; Researches on the Metamorphosis of the Alimentary Canal in Insects; on the Structure and Reproduction of Feathers; on the Height of the Meteor which projected Aerolites at Charonneville in 1811; on the Growth and Reproduction of Plants; on the Special Directions taken by certain parts of the Plants. The results of all his labours and a connected view of the subjects to which he devoted his attention, he gave in a volume entitled 'Memoires pour servir a l'Histoire Anatomique et Physiologique des Vegetaux et des Animaux.'

DUVERNOY, GEORGES-LOUIS, a distinguished anatomist and zoologist. He was born at Montbéliard, then a dependency of the duchy of Wurtemberg, now an arrondissement in the department of Doubs in France, on the 6th of August, 1777, and died at Paris on the 1st of March, 1865. His father practised as a physician at Montbéliard, and he was brought up to the same profession. He commenced his studies at Stuttgart in 1792; but the principality of Montbéliard having been ceded to the French in 1793, he was compelled to finish his studies at Strasbourg. He subsequently went to Paris, where he graduated in 1801. In 1802 he was associated with M. C. Duménil in reporting the lectures of Georges Cuvier, then in the zenith of his reputation. The "Leçons d'Anatomie comparée" were concluded and published in 1803. On the completion of this labour he married, and, as natural science afforded him little hope of support for a family, he retired to his native town to practise his profession. In 1806 he was recalled to Paris, and named by De Fontames joint professor of zoology in the faculty of science. Again, however, he returned to practice his profession in Montbéliard, and for nearly twenty years this distinguished zoologist pursued its harassing and laborious duties. In 1827 the chair of natural history in the faculty of science in Strasbourg was offered him: this he accepted; and from this time to his death we find him pursuing with unwavering industry zoological researches. In 1837 he was offered the chair of natural history in the College of France, vacated by the death of his great master, Cuvier. This chair he accepted, and held till 1850, when the death of De Blainville having created a vacancy in the chair of comparative anatomy he was appointed to it, and held it for four years. Duvernoy's contributions to zoological science are extremely numerous. In his writings and lectures he was more remarkable for the accuracy and extent of his knowledge than for the novelty and originality of his views. He was an industrious compiler, and was an extensive contributor to the 'Dictionnaire des Sciences Naturelles,' and also to the 'Dictionnaire Universelle d'Histoire Naturelle.'

DYNASTES, a genus of Coleoptera insects belonging to the section Pentamera, sub-section Lamellicornis, and family Dynastidae of M'Cleay. The species have the body very large and thick, the outer edge of the jaws serrated or toothed, and the lower jaws cornose and toothed. The genus Dynastes embraces the largest and most robust forms of the insect kingdom. They are nevertheless quite harmless. None of the species are found in this country, and only one in France. The largest forms are found in the tropical parts of India and South America. The habits of these insects are much the same wherever they are found. They bury themselves by day in holes in the ground, or in the decaying trunks of trees. At night they are seen flying about the trees. The females are more numerous than the males, and do not possess the horns, which give the males so remarkable an appearance. The more remarkable species of this genus are the Elephant and Hercules Beetles. The latter is of a glossy black color. In the males the thorax is developed into a thick and curved horn, which is bent downwards at the tip, and a similar horn projects from below which points upwards, so as to come in contact with the former. The entire length of this be-tie is 6 inches.

DYSART. [Firearms.]

DYSCLASITE, a Mineral consisting of hydromel siliicate of lime. It occurs in white fibrous masses, consisting of delicate fibres of a whitish or yellowish or bluish color. It has a hardness of 4½, and a specific gravity of from 2.28 to 2.36. It is easily galvanised in hydrochloric acid. It is found in the trap of the Faroe Islands. A variety called Olenite is from Greenland.

DYSDERA, a genus of Spiders. The species have 6 eyes, placed in a curve resembling a horse-shoe open in front; the mouth-caws very large, and produced in front; the maxillae strait, and dilated at the place of insertion of the palpi. The type of the genus is D. erythrina, which is not an uncommon species in Great Britain. It is mostly found under stones.

DYSODIL. [Coal, S. 2.]

DYSULITE. [Mineralogy, S.1.]
EARTH-WORM. [ANNEKLAU.]
EASINGWOLD. [YORKSHIRE.]
EAST INDIES. [INDIAN EMPIRE, S. 2.]
EASTBOURNE. [SUSSEX.]
EDELMEYER, JACQUES-JOSEPH, French chemist, was born July 10, 1814, at Aix-en-Provence, in France. Having passed successively through the colleges Henri IV. and Beaussac, he in 1831 entered the Ecole Polytechnique, and in 1833 passed from it to the Ecole des Mines. His ability and industry procured him, in 1835, the appointment of assistant, and in 1845 chief professor of analysis at the Ecole des Mines; in 1841 he was made one of the secretaries of the 'Annales des Mines,' and experimental chemist at the Ecole Polytechnique. A wider field was however opened before him by the appointment in 1847 of director of the Manufacture-Royale of Sèvres. To the duties of this office he applied all his energies. New and improved modes of operation, and the latest chemical discoveries, were employed with a view to economise the cost and improve the quality of the manufacture, while the most able designers and painters were called in for the purposes of obtaining the best models and the richest ornamentation; and under his direction the porcelain of Sèvres acquired a reputation fully equal to that of Sevres, while the establishment was regarded as a model for the conduct of its arrangements.

M. Ebelmen was a member of the commission sent by the French government in 1851 to the Great Exhibition, London. In the beginning of March 1852 M. Ebelmen was named examiner-chief of the mines, but he survived the appointment only a few days, dying on the 31st of March, 1852, in his thirty-eighth year.

Ebelmen was regarded with great hope for his combination of sound and minute scientific knowledge with practical abilities. He was a member of the Academy of Sciences, and his early death was generally regretted. He contributed a great many papers to the 'Annales des Mines,' the 'Annales de Physique et de Chimie,' and the 'Bulletins de l'Academie des Sciences.' Among the more important were: 'Sur la composition des carbes, and its employment in metallic manufactures;' and several upon the composition of rocks, the artificial reproduction of mine ashes, &c., of which we may note.—Sur les Produits de la Decomposition des espèces de minerais et leur composition, 1845; Sur une Nouvelle Méthode pour obtenir des Combinations Cristallines par la voie sèche, et sur ses applications à la reproduction des espèces Minérales, 1847; Sur la Decomposition des Roches, 1849, and particularly 'Sur les Altersations de la Végétation sous l'Induction des agents atmosphériques et des eaux d'infiltration,' 1851. The more important of his 'Mémoires' have been collected and published under the care of M. Salvetti with the title of 'Recueil des travaux scientifiques de M. Ebelmen,' 2 vols. 8vo, Paris, 1856. (M. Chevreul, Notice sur M. Ebelmen; Nouvelle Biographie Générale.)

ECCLESIASTICAL COMMISSIONERS. The Ecclesiastical Commissioners are a body corporate, created by the statute 6 & 7 Will. IV. c. 77, for certain purposes and with certain powers therein named. The great inequalities in the extent and income of the dioceses of England and Wales, in the duties and receipts of the cathedral and collegiate bodies, and in the extent of parishes and the annual value of the benefices of the Church of England, after long and angry comments gave rise in 1836 to the issue of two commissions, directing the persons named therein to consider the state of the dioceses with reference to the amount of their revenues, and the more equal distribution of episcopal duties; and of the several cathedral and collegiate churches, with a view to the suggestion of such measures as might render them more efficacious to the objects of the Established Church; and further, to devise the best mode of providing for the care of souls with special reference to the residence of the clergy on their respective benefices. These commissioners made four reports, recommending various alterations, and the appointment of permanent commissioners, for the purpose of preparing and laying before the sovereign in council such schemes as should appear to them to be best adapted for carrying those recommendations into effect; the Crown being empowered to make orders ratifying such schemes, having the full force of law. The statute above mentioned was passed in consequence; and under its provisions a great many beneficial alterations have been made and are being effected. The recommendations contained in the four reports of the original commissioners have also been carried out, with certain modifications and amendments, to which the sanction of Parliaments was required and obtained (see 1 & 2 Vict. c. 38, 106, 108; 2 & 3 Vict. c. 194; 3 & 4 Vict. c. 113; 4 & 5 Vict. c. 39; 6 & 7 Vict. c. 77; 10 & 11 Vict. c. 98, 108; 13 & 14 Vict. c. 41; 16 & 17 Vict. c. 60). The chief features of the alterations thus effected are the equalisation of the territorial extent of the dioceses, the creation of the new sees of Ripon and Manchester, and the union of the sees of Gloucester and Bristol. The revenues of the sees have also been equalised, by augmenting the income of the smaller out of the revenues of the larger. Cathedral and collegiate bodies have also been regulated. The powers and constitution of the Ecclesiastical Commissioners have been amended by the stat. 3 & 4 Vict. c. 113, s. 78; and by the appointment of Church Estates Commissioners, who are commissioners in the Ecclesiastical Court of the United Kingdom, by the ecclesiastical members of the Ecclesiastical Commission (13 & 14 Vict. c. 14; 14 & 15 Vict. c. 77). The Ecclesiastical Commissioners are the only body of persons permitted to exercise any power over the clergy of the Established Church or over the property of those clergy; and, lastly, by the transfer to them of the powers of the Church-Building Commissioners.

ECCLESIASTICAL COURTS. Until recently the Ecclesiastical Courts, in addition to their merely spiritual functions, had cognisance of three kinds of civil cases, namely, causes pecuniary, causes matrimonial, and causes testamentary.

The first of these heads included matters relating to the non-payment of tithes, many of ecclesiastical dues and fees, and also matters of spoliation, dilapidation, and neglect of repairing the church and things thereto belonging. The statutes under which the tithes have been commuted and replaced by rent-charges, recoverable by distress like other rent-charges, have virtually abolished suits for tithes in the Courts Christian, and their jurisdiction in other causes pecuniary has thus been in other ways reduced to a very small compass. The statute 20 & 21 Vict. c. 89 has entirely abolished the jurisdiction of these Courts in cases matrimonial (Divorces, S. 2). The privilege of granting marriage licences being alone preserved to them. And the Act of the same session (20 & 21 Vict. c. 77) has transferred their jurisdiction in cases testamentary to a Civil Court, proceeding according to the course of the Common Law. The clauses of the statute 21 Geo. III. c. 100, emended by 22 Gra. II. c. 28, relate to the dividing of lands held in tail, and the partition of such lands, and the distribution of the estates of intestates. To these clauses Title 3 of the statute 1 Geo. IV. extends the words 'and in all cases where the death of any person shall give a right to any person to call for an administration of his estate, or to recover from any person any part of the estate of such deceased person.'

 Việc bị cắt:

ECHELON (or French Echelons). A genus of fishes belonging to the section of Sub-Brachial Muscles, corals, and the family Echeloniidae. The body is elongated, covered with very small scales; a single dorsal fin placed opposite the anal; the head very flat, covered with an oval disc formed by numerous transverse cartilaginous plates, the edges of which are directed backward; the mouth wide, with numerous small recurved teeth on both jaws, the tongue, and the vomer. (Yarrell.)

The species of this genus are not numerous. Cuvier enumerates four; and another has been described from the west Indies. They are all easily recognised by the peculiar adhesive disc on the top of the head, by means of which they attach themselves to other fishes, the bottoms of vessels, or other objects floating in the sea. The object of this contrivance is not very well ascertained.

E. remora, the Common Remora, or Sucking-Fish, is found in the Mediterranean Sea, and was known to the Greeks and Romans. Dr. Terton once took a specimen of this species riding on a cod-fish in Swansons Bay. The following is Mr. Yarrell's description of it: 'The disc of the adhesive apparatus in the specimen now described, with seventeen transverse lamines, was one-third of the whole length of the fish, not including the caudal rays, the breadth one inch and one-quarter. The mouth is free, flexible, and of considerable breadth, to secure perfect contact with the surface to which it is opposed; the parallel
laminae are represented as only slightly elevated: the degree of adhesion is in proportion to the power used to raise the lamina, and the direction of the rise is in a direction perpendicular to the plane of contact. * * * * The vertical direction of the moveable lamina is effected by sets of muscles going off obliquely right and left from two elongated bony processes, one on each half of each of these moveable divisions. The contraction of these muscles acting upon these levers, raises the external edges of the parallel divisions, increasing the area of the vacuum; and it will be observed that the points of the moveable transverse divisions to which the edges of the body are attached, are the farther than the outer edge, by which the chance of interfering with the perfect continuity of the free margin, and thereby destroying the vacuum, is diminished. All the bony laminae, the outer edges of which are united with some of the teeth, are, on the contrary, moved simultaneously, like the thin vertical divisions of our common window-blinds, by means of the mechanical contrivance on the framework. The longer muscles placed nearer the outer oval edge are probably instrumental in preserving the contact of the more flexible margin, and the serrated external edges of the parallel laminae help to preserve the degree of elevation obtained: the adhesive power as before observed, is in proportion to the area of contact to the volume of the body treated.

ECHIVERIA, a genus of Plants named after M. Echiveri, author of the 'Flora Mexicana.' It belongs to the order Crossales. It has a 5-parted calyx, the sepal s erect, united at the base. Petals united at the base, erect, three at the base, the middle one lower, nearly serrated at the base, acute. Stamens 10, shorter than the petals, and adnate to them at the base. Scales 5, short, obtuse. Carpels 5, ending each in a satulate style. The species are succulent shrubs, natives of Mexico. None of the species are native in the arts or medicine, but their handsome leaves and showy flowers give them a place in every collection of plants. The genus is closely allied to Sedum, and many of the species resemble that genus.

ECHIODOIDES is a genus of Apical Malaconogryphus Fishes belonging to the family Muraenidae. The head is oval; jaws furnished with large cylindrical teeth in front; other smaller teeth on the palatal bones and on the vomers. Gill-apertures large; branchiostegous membranes with seven rays. Body smooth, without scales, elongated, compressed. Dorsal and anal fins nearly as long as the body; all the rays soft; no ventral fins; anal aperture near the head. This genus was constituted to receive a very remarkable fish (E. Bavaricus) found in the Danube at Capua, in the province of Avellino, near Glenarm, in the county of Antrim, Ireland. It was described by the late Mr. W. Thompson in part ii. vol. ii. of the 'Transactions of the Zoological Society.' This fish resembles the infamous charaxes, and Mr. Thompson had some difficulty in determining the total length of the fish was 11 inches. As Dr. Drummond's specimen is the only one on record, nothing is known of the habits of the fish.

ECHYMOTERES (Fitsinger), a genus of Sciuere belonging to the family of the Laamiiidea. It possesses the teeth and pores of the genus Polychrus, but with small scales on the body only. The tail, which is large, has great scales, which are rhombic and crenated. The head is 4-sided, and covered with small plates. The form of a little short and fat-tailed, like that of some of the Agonyl, rather than like the slender shape of Polychrus. There are four species—E. Fitsingeri and E. anulatus, natives of Brazil; E. obtusirratis, native of Mexico; and E. cucullotis, a native of Brazil.

ECTOZOA (from ecto, without, and bodi, living), animals found living upon the external parts of other animals. This term is applied to distinguish the forms of animal life which are parasitic upon the parts of an animal and not from that animal which inhabit their interior. [Ectozoa.] Whilst those which inhabit the interior of animals have so much resemblance to each other that naturalists place them together in an order which they do not feel to be a separate Order; those which are found on the surface are very dissimilar, and belong to different and similar families. The term Ectozoze is therefore not one expressing any affinity between the animals included in it, but simply refers to their habitation.

The Ectozoze as well as Ectozoa are found frequently associated with the diseased states of the animal bodies on which they are found, and much discussion has arisen as to whether

there is the true cause of the diseases which they accompany. Too much is certainly true, that when they originate from the diseased state of the body on which they are found, when allowed to increase they become themselves a source of diseased conditions, which disappear as soon as they are destroyed.

The general law equally applicable to parasitic plants as well as to animals. So that it would appear that, although their first attacks may be invited by a diseased condition of the plant or animal on which they are found, they may be productive of destructive effects by an unnatural and unholy influence, and may become the source of destruction by the attacks of other animals. Under the term Ectozoa a number of animals have been placed together whose claims to be regarded as sections of the great family Cestodes are now generally recognized. These are found more especially on the bodies of fish, infesting their skin, eyes, and gills. They are very numerous, and the larger number of them belong to the family Lenormand. [Lenormand.] They must be regarded as the Ectozoa of aquatic animals. The bodies of the Cestozoa are frequently the chosen residence of many species of Curripedia. [Cirripedia.]

Land animals are subject to the attacks of various forms of Ectozoa, more especially those belonging to the Articulate tribes of animals. The following is a list of the creatures to which man is subject in various parts of the world.

Pediculus canis (Dog's Flea), the Crab-Louse; Pediculus Ovatus (Nitsch), Head-Louse; Pediculus Vesticum (Nitsch), Body-Louse; Pediculus Tectosum, Bed-Mite (Anoplura, S. 2); Sarcoptes Scabiei (Linn.), Itch-Insect [Acari], Dermanyssus Boty (Gervais), Louse American; Dermanyssus granulosus (Linn.), Argentine; Dermanyssus penetrans (Gennel), Chigoe; Pulce irritans (Linn.), Common Flea [Pulex]; Omea lenticularis (Linn.), Bed-Fug [Boo]; [Omea hominis (Say), Gaq-Fly [Bom].

Other creatures are occasionally found taking possession of the surface of the human body. In diseased conditions the common fly has been known to deposit its ova in various parts of the body, and many of the insects which are parasitic upon the lower animals will take up their abode on the diseased parts of man. Thus Anopheles, a mosquito which is peculiar to America, and is the species of animal on which they are found, so also with the species of the genera Pulce and Omea.

EDGECOMBE. MARIA, the daughter of Richard Lovell Edgeworth, by his first wife, was born on January 1, 1767, at Harle Hous, leading a most secluded life. In the year 1782 her father went with his family to reside on his estate at Edgeworthtown, until when, except for a few months in her childhood, her daughter had never been in Ireland. From that time however Edgeworthtown became her abode, and she lived there the remainder of her long life, with the exception of occasional visits of a few weeks only to England, Scotland, and France, and for about two years at Chloton in attendance on her sick step-mother. The neighbourhood of Edgeworth- town did not afford much congenial society, the family of the Earl of Granard, and Pakenham, the Earl of Granard at Castle Forbes, and that of a Mr. Brookes, being the only ones whom they visited; and Pakenham Hall, she says, was twelve miles distant, with a vast Serbonian bog between us, with a her long life, with the exception of occasional visits of a few weeks only to England, Scotland, and France, and for about two years at Chloton in attendance on her sick step-mother. The neighbourhood of Edgeworth-town did not afford much congenial society, the family of the Earl of Granard, and Pakenham, the Earl of Granard at Castle Forbes, and that of a Mr. Brookes, being the only ones whom they visited; and Pakenham Hall, she says, was twelve miles distant, with 'a vast Serbonian bog between us, with a her long life, with the exception of occasional visits of a few weeks only to England, Scotland, and France, and for about two years at Chloton in attendance on her sick step-mother.
Einleitung

1834, Orlandino, extends its length after the joined but somewhat different line of the Eifel. It was opened by Miss Edgeworth's works, which were published several years ago in a collected series. The manner in which they describe, especially those of fashionable life, belong to the same degree to a past generation. But their delineations of character, more particularly of Irish character, are so true to nature, and there is such a vein of quiet humour and practical good sense running through them all, that amidst the more exciting plots and strong situations of the novels of our own time, the more important may be referred to as worthy of a lasting place in our literature.

Miss Edgeworth passed a quiet but useful life with her family; she maintained an extensive correspondence with many friends and literary acquaintances, and at length died May 21, 1849, at the venerable age of 83.

EDG. ELEONOR

EDMONTON. [MIDDLERS.] ELE. SAND. [AMONTYNS, N. J.]

EGG. [REPRODUCTION. S. J.]

EICHORN, CARL FRIEDRICH, son of Johann Gottfried Eichhorn, obtained considerable celebrity as a able and learned jurisconsult. He was born on Jan. 20th of 1795. After passing through the usual course of academic and legal training, he was named in 1805 professor of Roman Law at Frankfort-on-the-Oder. In 1811 he removed to Berlin, and, in 1815, was named professor of the Law, in each place holding the same chair as at Frankfort. Ill health however compelled him in 1828 to resign, and to retire to an estate he possessed near Tübingen. Having somewhat recovered, he was in 1831 again summoned to Berlin, and along with his professorship he received an appointment in the ministry of foreign affairs. At length in 1833 he resigned his professorship, and devoted himself entirely to his official duties and to writing. About this time he was regarded as the ablest authority in Germany on the subject of the Roman Law, and of the commission of legislation. He died in July 1854.

Carl Eichhorn was one of the most erudite exponents of the ancient Germanic law, of its origin, its growth, and its various bearings. As the associate and fellow-labourer of Savigny, he was able to bring the different branches of the subject as the main object of his investigations, and as holding the chair of German law for so many years, Eichhorn exercised an important influence on the study of law in Prussia. His principal writings are—Deutsche Staats- und Rechts-geschichte, 4 vols. Svo, Göttingen, 1806-15, which work has passed through eight editions; Grundriss des Kirchenrechts der Katholischen und Evangelischen Religionspartei in Deutschland, 2 vols. Svo, Göttingen, 1831-33; and Einleitung in das Deutsche Privatrecht, mit Einschrankung des Lehrbuchs. In conjunction with Savigny and Geschoß he also carried on the Zeitschrift für geschichtliche Rechtswissenschaft, Berlin, 1815-1843.

Eichhorn's Almanach in the Rhine-Provinz, extends along the left bank of the Rhine between Bonn and Coblenz. Its proper geographical boundaries are the Rhine on the east, which divides it from the Westerwald; the deep valley of the Moselle on the south, which separates it from the Rhineland and the Hunsrück, north-eastern offshoots of the Voges; the Our or Ourthe, the Ardennen hills, and the Meuse on the west; and the great flat plain of the Lower Rhine on the north. The name however is confined to the region that stretches eastward from the German Rhine, and extends to the Moselle. The head of these rivers lies an extensive highland called Petersberg, or Paanss (from the Celtic pecs bagi)—a dreary waste covered with turf-bogs, mosses, and reeds, and rising between 1800 and 2000 feet high, with a length of about 16 miles every way, which connects the Eifel with the Ardenne,

and offsets of which stretch nearly to the Menser below Aix-la-Chapelle.

The Eifel is a rugged, desert, and in parts swampy table-land, with the exception of 1400 to 1600 feet above the Rhine. Its slopes are scored in places by deep forests, and valleys, which are traversed by tributaries of the three great rivers named above. The flat surface of the table-land with the exception of some rather extensive forest-tracts, presents a barren, marshy, and barren soil; but here and there rise up abruptly narrow crags and cones of various elevations, some of them richly wooded, with wide-spread layers of ancient lava between. The general condition of the region is clay, flint, limestones, and slate; but the hills and rocks in some places are craggy, and the ravines, and glets of the Eifel are in many instances composed of basalt or caved in with it; indeed the Eifel almost everywhere bears traces of violent convulsions and volcanic actions. Extinct volcanoes, cauldron-shaped depressions, tarns of circular shape filling up ancient craters and locally called 'Maare,' mineral-springs, lava-streams, columnar basalt, fossil zoophytes and shells, showing submergence under some ancient waters, are among the natural curiosities of this interesting region.

Amongst the highest points in the Eifel the following may be mentioned:—The Hohen-Acht, above Adenau, 3244 feet above the sea; Nürberg, which is also near Adenau, and is crowned with an extensive feudal castle, 2621 feet; Kelberg, near the source of the Oos; Michaelberg, near Müntersalve, 1600 feet; and the Schneifel, or Snow-Eifel, in the circle of Prüm, in the wildest part of the region, 2100 feet.

The Eifel is a length from east to west, between the Rhine and the Our, of about 50 miles. Along the left bank of the Rhine, north of Andernach, it extends for about 20 miles; but in the interior the breadth is in some places more, in others less than this. Rivers flow from it in all directions. On the northern side of the land (a small town in the government of Cologne with about 1600 inhabitants), rises the Eifel, which flows with rapid course down into the low country, and enters the Rhine at Grimburg. Further to the south is the great Flüss, on which, which flows westward, rising in the mountains between Malmedy and Montijo; after reaching the low country it runs north-westward past Düren and Julich, and, belonging Belgian Limbourg, joins the Meuse on the right bank at Kerneuburg, and flows in a course of about 80 miles. Both of these rivers sweep down the stone and gravel from the highlands; they are subject to frequent and sudden swells, and abound in fish. Their water-power is turned to use, and the town of Düren itself is supplied with water from them. Before it leaves the Eifel the Rhine receives on its right bank the river of the Eifel, which rises near Blankenheim, and passes Gemünd, a small town in the government of Aachen with about 1000 inhabitants, who manufacture woolen-cloth and leather. Not far from the town the Rhine, which rises in the mountains between Past Malmedy, and throws itself into the Ambrève, a feeder of the Ourthe, in the Belgian province of Liège. The Ambrève itself rises a little south of the Warthe, which it joins a little below Malmedy. Malmedy, a town in the government of Aachen, stands on the Warthe, and has about 4000 inhabitants. It is a quietly-built place; the houses and gardens are all in the Dutch style. The town is famous for its manufacture of sole-leather; there are above fifty tannery yards, and the manufacture of leather, and of some woolen-cloth, lace, soap, potash, and glue. Monsiande stands in a marshy country between two high hills on the left bank of the Warthe, and has a population of 3000, who manufacture wools-stuffs, leather, and iron. A large, strong, and gloomy castle above the town is said to occupy the site of a hunting-seat erected here by Charlemagne: it is a fine specimen of a feudal fortress.

On the southern slope flows the Our, which passes Renland and forms a branch of the Warthe, and is exemplary between Rhenish Prussia and the Dutch province of Luxemburg. The mouth of the Sure, a feeder of the Moselle. The Sure receives also from the Eifel the Prüm, which rises in the wildest part of the district. Just above its junction with the Warthe the Prüm has a number of small vilages, and is in the government of Trèves. It is situated to the north of the Schneifel at the foot of a beautifully wooded hill, and has 2100 inhabitants. Its name is taken by corruption from that of the Benedictine Abbey of Ad Praxm, founded here in the 8th century, and in which Pope, natural son of
Charlemagne, and the emperor Lothaire were monks: the latter died here a.d. 853. The abbey buildings were destroyed by fire in 1789, with the exception of a small portion which is of the Italian style, and which has since been rebuilt near the ancient foundations.

The road from Aix-la-Chapelle to Trèves passes through Prüm, and coincides at some points with the old Roman road from Cologne to Gelnhausen, of which a portion is the western part of the Millstatt. The old town of Prüm, which lies about 9 miles to the north of Prüm. Near Distel, is the ancient Bedeck Vicks, a town of about 2000 inhabitants, midway between Prüm and Trèves, a Roman villa, in excellent preservation, and two Roman milestones, set up in the reign of Hadrian, which are of interest to collectors.

Southwards also, and near from the source of the Roer, flows the Kell directly into the Moselle a little below Trèves. At Gerolstein, a picturesque little town of 600 inhabitants, on its left bank, the river runs between cliffs of limestone and sandstone, in the lower part of which is the castle, dry crater, the surface of which is cultivated, several old lava streams, caverns, basaltic rocks, and mineral springs. Fossil shells and corals are found strewn over the fields at Auberg, in the neighborhood of Gerolstein. Olivine and pallasite are found among the dry craters of Dreiser-Weihen, about six miles east of Gerolstein.

Further east, but still on the Moselle slope of the Eifel, flows the Lieser, the Us, and the Elz. The Lieser passes Duin, an inhabited town of 1200 inhabitants, near the town of Li-ter, which has a population of about 1000. At the village of Duin, which has an old castle (the family residence and birth-place of Marshal Dauin, who led the Austrian armies in the Seven Years War), there are three massive walls erected from the former partition of the rock. To the southward of Duin and on the left bank of the river, is the village of Mandelscheid, famous for its old castle and for the basaltic marble in its neighbourhood. On the hill of Mosenberg near it are the two volcanic cones of slag, from one of which a lava stream descends to the valley of the Lieser. The Meerfelder mass is about 100 fathoms deep, and the Pulver mara, one of the largest and most beautiful of the crater lakes in the Eifel, is 200 feet below the sea level. The village of Struthschen is built in a dry crater.

The Lieser rises not far from the source of the Us, and flows south-east down a wooded gorge, in which it makes innumerable windings, bounding from side to side against the cliff on the left. On the way, it crosses the little village of Mosel-Kern. The Els forms some pretty cascades, and passes the castles of Pyrmont and Elz. The Els-Schloss is one of the most picturesque and best preserved old ferral forresses in Europe; it begins to yield to decay but is still inhabited. On the opposite rock stands the rival castle of Trutz-Els, erected by the Bishop of Trèves, against the lords of Elz. The castle of Pyrmont was burnt by the Swedes in 1641. Between the mouths of the Us and the Elz, on the left bank of the Moselle, stands the town of Kochen, prettily situated on a hill, with two old castles frowning from the adjacent heights. Although a pretty object from the Moselle it is a very dirty place. Population 2000.

On the eastern slope flows the Nette and the Ahr. The Nette rises to the east of Adenau, and runs first to the southeast and then eastward into the Rhine a little above Anderach, which town has been already noticed. [Annenach.] The Ahr rises by the Hardenberg T and running northeastward through a valley abounding with wild and most picturesque scenery, past Altenahr and Ahrweiler, enters the Rhine between Remagen and Sinzig. In the upper part of its valley the Ahr is joined by the left bank of the Adenau near the small village of Adenau, and over the hill of Landskrone in the Arththal, are ruins of a castle built by the emperor Philip of Hohenstaufen in a.d. 1205. The Ahr is celebrated for its minnows, trout, and craw-fish. A fine road runs up the valley and in parts is carried by tunnels through the rocks. Adenau, is a small town of 1300 inhabitants, at the foot of the Hope-Acht. Ahrweiler, is a pretty walled town entered by four gates, and has about 2500 inhabitants, who are chiefly engaged in the growth of the vine. It is the centre of the wine trade of the valley, and has a beautiful gothic church erected in the 13th century.

The Brohlbach, a small feeder of the Rhine, enters that river near the castle of Brohl, a small village, midway between the mouths of the Nette and the Ahr. It is supplied with water from the Eifel, paper-mill and several terraces, in which the volcanic tufs, quarried in the neighbourhood, is ground for exp-rt to Holland; the tufs, reduced to dust, is used by the Dutch for making cement, or lime, or for many other purposes. In the tufs quarries in the valley of the Brohl, land shells and trunks of trees r-rduced to the condition of charcoal, are found imbedded. Mineral waters, resembling Seltzer, are got from springs in the valley of the Brohl. A little north of Brohl is the castle of Rheineck, recently repaired by Professor Bethmann Hollweg, of Bonn. Sinzig is a small ill-built walled town of about 1600 inhabitants, with an intere-t-ting gothic church, erected in the beginning of the 12th century; an adjoining chapel contains a natural mummy which was carried away to Paris and the French extended their frontier to the Rhine, but was restored at the peace. Sinzig occupies the site of the ancient Septinium, near which is the town of Siglo.

The town of Prüm runs along the left bank of the Rhine nearly coincides with the present diligence road between Bonn and Cologne. Remagen, a small place of 1400 inhabitants, is occupied by the Eifel Hypogea. Roman sub-quoties have been found here.

About 6 miles inland from the mouth of the Brohl, is the large and beautiful crater-lake of Lach, or Lacher-see, about 2 miles long and about a mile and a half broad, and so deep increases towards the centre where it is 214 feet deep. The lake is hemmed in on all sides by a ridge of hills covered with wood down to the water's edge. It is supposed to have been formed by an effusion of volcanic gases issuing from an opening on the north-east side of the lake; and in a neighbouring pit bodies of birds have been found killed by the noxious vapour, which circumstance has given rise to a popular notion similar to that connected with the Nemi lake in Italy, that the birds fly over the Lachsee. The lake is fed by numerous springs beneath its surface, which keep its basin always full. Its waters are clear, deep, blue in colour, very cold, but never freezing; and abound in a great variety of fish. Some of its volcanic origin, but the superstructure is carried off by an underground current very nearly a mile long, cut in the 12th century by the Benedictine monks of the now ruined abbey of Lach, which is a little south-west of the lake. The shores of the lake are covered with masses of basaltic rock, and in some places the old church of the abbey, or Kloster-Lach as it is called, was suppressed at the time of the first French revolution. Part of the old buildings that remain is now converted into a farm-boste; the church, a beautiful specimen on a small scale of the round-arched gothic, erected in the early part of the 12th century, has been purchased in order to preserve the Frisian government. In the gardens of the abbey, the lake and village of Lacher, are favourite places of resort with the Frisians. The lake is named after the ancient Lach valley, and the ancient Lach, or Lacker, are several millstone quarries, a paper-mill, tan-yards, and mineral springs. To the geologist, the botanist, and lover of the picturesque, all the southern and eastern part of the Eifel is extremely interesting. Besides the Lacher-see, there are a great number of other most extinct craters, exist between the Nette and the Ahr.

The climate of the table-land of Eifel is damp, and much colder than that of the plain of the lower Rhine; cold misty fogs frequently hover over it. In all Prussia there is no place so poor in arable land as the Eifel. The rugged surface
the region is covered with wild heath or swampy bog, the thin casing of the soil not affording nourishment for the roots of the trees. Some parts of it however, as before stated, are clothed with forests. This is especially the case in the districts covered with volcanic deposits. The chief species of forest trees are beech, oak, and fir, which are grown for the supply of fuel and timber, the species of which the forests are inhabited, and in these the population is gathered into small towns, villages, and hamlets, most of which have sprung up under the favorable protection of some feudal castle, and a few of which have been abandoned. The rapid slopes along the Ahr valley and towards the Rhine, vines and fruit trees yield valuable crops; here every piece of cultivated land is covered with walnut, apple, pear, or cherry trees. The wine of the Ahrthal is of excellent quality.

Richard Riibenach, of Bonn, said, that in the lower parts of the region annually from Cloppenburg for cherries. Walnuts are a favorite crop in the hills but not in the valley bottoms, where it is said, the leaves of the walnut tree injure the soil. The nuts are preserved for oil. Apples and pears are sliced and strung upon pack-thread to serve as vegetables in winter. The fruit of the valleys of the Eifel is good generally; but the apples and pears grown on the Moselle slope are particularly delicious, and not surpassed by those of any region in the province. Grapes are also grown, the number of which is restricted in quantity; the deficiency is supplied from the neighboring districts.

The region of the Eifel is exposed to a phenomenon called Wolkenbruch, or Cloud-Burst, being a sudden discharge of water, from heavy clouds. The torrential rains, intense thunder and lightning, which may strike; trees are rooted up and hurled down by suddenly formed torrents; cattle, houses, soil, and crops are swept away. A cloud-burst of this description destroyed the greater part of Mittenscheidel in 1611.

The principal roads through the region of the Eifel are those from Aix-la-Chapelle to Trèves, and from Cloppenburg to Bonn; the high road up the left bank of the Moselle from Cloppenburg to Trèves, and the new road up the Ahrthal to Trèves. The prosperity of the region is not nearly as great as the stories of the roads, but most of these are bad. The great Roman road made by Agrrippa from Trèves to Cologne traversed the western part of the Eifel. Along it were numerous post houses (mutationes) and six "manstane," serving as military posts and hotels. Busch, vicus, now Bitburg, was one of these "manastane." Zelzach (population 1900), near the Nassel, a feeder of the Erft in the plain, at the northern base of the Eifel, was another of the manstanae, and was called Tolbiacium. The road is still in a perfect state at Zelbach. Remains of an aqueduct, which ran from the Erft to the town, and of just such aqueducts as the stations with water, are still visible at ten or a dozen different places between the two cities. The road along the left bank of the Rhine, between Remagen and the precipitous projection of Rolsandrucks, has been laid down and is bad, and connected with the ruins of an old castle, is cut in the rock. In making this part of the road several Roman remains were found. Connected with Rolsandruck is the circular crater of Rodersberg, which is a quarter of a mile across and 100 feet deep; its sides, which are composed of tufa and scorion, are cultivated. The castle of Godtberg, a town of about 1000 inhabitants, a short distance north of Rolsandruck, is an interesting object on the road and from the Rhine. Between Godtberg and Bonn, at the north-eastern extremity of the Eifel, and the coal and iron mines are still a few miles from the town, and their ditches are not much more than twenty or thirty yards from their edge. The coal is said to be of the kind called lignite or fossil wood, and has evidently resulted from the subidence of some primeval forest; fossil fishes, fresh-water shells, and very fine and beautiful moss live in the springs, and the coal is a very easy and expedient remedy to landlords whose tenants are in arrear, or who hold over after their term has expired or been determined. The Common Law Procedure (re-enacting 1 Geo. IV. c. 67) allows a landlord, on serving a writ of ejectment to a tenant holding over after his term has expired or been determined, to give him notice that he will be required to give bail (if ordered so to do by the court or a judge), conditioned to pay the costs of the suit and damages in case of an adverse judgment. If bail is thereupon to be given, or the tenant fails to do so, the claimant obtains immediate judgment for recovery of possession and for his costs. In ejectments also between landlord and tenant the claimant may go on, after proving his right to recover, to give a writ of mesnes profits, and the jury shall thereupon give their verdict on the whole matter, both as to the title and mesne profits; so that in such cases a second action for mesne profits is unnecessary. Besides these remedies a landlord may, in cases where the rent or mortgaged debt has been paid, proceed in the County Court (19 & 20 Vict. c. 108, ss. 50-58). And if the rent does not exceed 20L, and no fines has been paid, he may proceed summarily before the justices in the petty sessions (1 & 2 Vict. c. 72). (Blackstone's "Commentaries," Mr. Kerr's edition, vol. iii., p. 210.)

John Dow's suit was attended with one great disadvantage; it could only be followed out during the year, and so that, if a right to lands in Yorkshire accrued on the 1st of June, the person entitled was unable to bring his adversary into court before the following November, or in case of a defence, to proceed to trial before March in the following year. The fictions on which Old English law was founded were now found objectionable, and accordingly, when the procedure of the Superior Courts of Common Law was reconstructed in the year 1852, a new mode of proceeding for the recovery of lands or rents was created, which possesses the one distinguishing peculiarity of the old action, that in it no question can be raised except that of title.

This new action is commenced by the issue of a writ, directed to the persons in possession by name, and to all persons entitled to the property as from the commencement of the term; and it isua; and commands the persons to whom it is directed to appear within six months to defend the possession of the property claimed; a notice being added, that, in default of appearance, they will be turned out of possession. This writ is served on the tenant in possession, or, in case of a vacant possession, by posting a copy thereof upon the door of the dwelling-house, or other conspicuous part of the property. Every tenant served with a writ must give immediate notice thereof to the landlord, to enable him to take possession and to rack rent of the premises held by him. The object of giving the landlord notice is, that he may be permitted to defend, which he has a right to do, for frequently the tenant has no interest in the premises beyond the temporary possession. A writ of ejectment, unlike a writ of possession, does not authorize the tenant to defend the possession; for possession has now become the very essence of property, twenty years' uninterrupted possession constituting a title good against all the world.

If no appearance be entered, the claimant obtains judgment to recover possession of the land claimed; which he does by the writ asserts his right. By entering an appearance, the tenant, or the landlord, or any other person admitted to defend, denies that right. The parties are then at issue on the writ, and the next action which the claimant must prove is the landlord's right to a writ on the trial, which must take place, in all ordinary cases, in the county where the property is situated; the proceedings at and after the trial being the same as in ordinary actions.

Such is the modern way of trying the title to lands and tenements. It is founded on the same principle as the ancient writs of assize, being calculated to try the mere posse- 
sions title to an estate; and has succeeded to those real actions, as being infinitely more convenient for attaining the end in view; and it is probable that the practice of giving a very easy and expeditious remedy to landlords whose tenants are in arrear, or who hold over after their term has expired or been determined. The Common Law Procedure (re-enacting 1 Geo. IV. c. 67) allows a landlord, on serving a writ of ejectment to a tenant holding over after his term has expired or been determined, to give him notice that he will be required to give bail (if ordered so to do by the court or a judge), conditioned to pay the costs of the suit and damages in case of an adverse judgment. If bail is thereupon to be given, or the tenant fails to do so, the claimant obtains immediate judgment for recovery of possession and for his costs. In ejectments also between landlord and tenant the claimant may go on, after proving his right to recover, to give a writ of mesnes profits, and the jury shall thereupon give their verdict on the whole matter, both as to the title and mesne profits; so that in such cases a second action for mesne profits is unnecessary. Besides these remedies a landlord may, in cases where the rent or mortgaged debt has been paid, proceed in the County Court (19 & 20 Vict. c. 108, ss. 50-58). And if the rent does not exceed 20L, and no fines has been paid, he may proceed summarily before the justices in the petty sessions (1 & 2 Vict. c. 72). (Blackstone's "Commentaries," Mr. Kerr's edition, vol. iii., p. 210.)
The elements of Elastic Tissue are cylindrical or band-like fibres with dark contours, very minute, and when present in large numbers they exhibit a yellow tint, which it has been called Yellow Tissue. The fibres acquire sometimes little cavities in particular spots, which give these fibres a striated appearance, as seen in the giraffe. The elastic tissue is rarely found in large masses, but is very frequently mixed with areolar tissue, and occurs in the networks or organs into which this tissue enters, and constitutes their special feature, are—

1. The elastic ligaments, in which the tissue, with only a slight admixture of connective tissue, is rarely, if at all, seen, and it is only rarely that the areolar tissue is contained in the fibres.

2. The ligaments of the heart, the ligamentum nuchae, the ligament of the larynx, and stylo-hyoid ligament.

3. The dura mater, which appear either in the form of fibrous networks or of fenestrated membranes, and are found in the walls of the vessels, especially in those of the arteries, in the trachea and bronchus, and in the fascia superficialis.

**Election.** The proceedings on the election of knights and baronets to the Commons House of Parliament have formed the subject of several recent statutes; all of them, moreover, are based on the principle of not taking up more than one vote at an election. *With this view, the elections, alike in counties and boroughs, must now be completed in one day, so that neither time nor opportunity may be allowed of extensively tampering with the voters.* The thoroughly formal proceedings are still taken under the original Reform Acts; but the bribery oath can no longer be administered to a voter. In order, however, to restrain bribery, treating, and intimidation, the returning officers are now required annually to appoint election auditors, who can alone account for the respect in which the election is paid by the candidates. Stringent provisions have been made for inquiring into charges of corrupt practices, by Committees of the House, sworn to the performance of their duties. Bribery, if proved, involves the disqualification of the elector, and the disqualification of the member chosen if the charge is brought home to him. The candidate is required to appoint his own agents, in writing, so that they may be known; and to send all accounts and a note of all his money spent in connection with the election to the returning officer; which, when audited and paid through the auditor are to be published in the local newspapers. It may be added here, however, that both the method of proceeding at elections, and the principles which ought to guide legislation on that subject are at present under consideration; the present method is being only of temporary operation and of an experimental character. (Blackstone's "Commentaries," Mr. Kerr's edition, vol. i. p. 168.)

**Electric Telegraphs.** In the previous Supplement a full account of the discovery and of the application of the electric telegraph was given. ([Telegraph, Electro.) All that remains now is to complete the account by a statement of its more important improvements, and more especially of the success and rapid descent of messages by submarine telegraphs, bringing the most distant countries into almost immediate connection.

At the present time almost every important town in Great Britain, with the exception of Inverness in the far north, and Plymouth in the south-west, is furnished with means of telegraphic communication to other towns. As fast as any new railways, whether trunk or branch lines, are opened, so surely is the telegraph now laid down; insomuch that the length of telegraph is nearly coincident with the length of rail. The extension of this railway is such as to disturb the simplicity of the rule itself. From Cornhill, from Charing Cross, from the government offices, and from numerous other places in the metropolis, messages are every day sent, not only to Edinburgh, but to Aberdeen in one direction, to Liverpool in another, to Dover in a third, to Southampton in a fourth, to Plymouth, to Milford Haven, to Holyhead; indeed, to almost all of our outports, and to nearly every inland town of any commercial pretentions. A system is everywhere acted on that the principal railway stations shall at the same time be telegraph stations, some of the wires being for public use, and the others for railway use. The charges have been reduced to a great extent, to the great satisfaction of all parties; and the messages now sent are of countless variety—the price of funds, the state of the markets, orders to purchase, the arrival of ships, the receipt of important news, the Queen's speeches, the result of elections, the divisions in Parliament, and a thousand other things. The wire may be seen while travelling, the state of the weather, the verdict of an important trial, the sending for a doctor, the detection of a thief or murderer, inquiries after health, announcements of illness or of death, inquiries after lost luggage—these are things which are daily sent over the wires, and are often confided to communications intrusted to the copper wires.

In most parts of England the wires, as from the commencement of the system in this country, are supported on poles at a height of several feet from the ground, in a few cases, such as along the coast-road from London to Dover, a subterranean arrangement has been adopted: the wires being encased in a wooden trough, and deposited a foot or two beneath the surface of the ground. This is also adopted in the streets of London, and of other large towns.

An interesting use of the sub-way telegraph may be here noticed. In proportion as the use of Greenwich time has become familiar on all the English railways, so has it become impossible to regulate these, when at a distance from the principal station. So a wire has been carried from the Observatory, through Greenwich Park, and across Blackheath to the Lewisham station of the Kent Railway; thence to the London Bridge station; and thence to the South-Eastern station in the Strand. The top of this office has been erected a hollow shaft, up the interior of which the electric wire is carried, and a large light ball, capable of moving eight or ten feet vertically, slides easily up and down near the top of the shaft. At ten minutes before one o'clock each day the ball is raised nearly to the top of its shaft or spindle; and at five minutes before one it is raised quite to the top. At one o'clock precisely, exact to a single second, the great or master-clock at Greenwich Observatory puts in action a small piece of mechanism which sends an electric current through the wire to the Strand; the wire at this end is connected with another piece of mechanism, which releases the ball and allows it to fall suddenly. The ball falls upon a kind of piston in an air-cylinder, so that at any moment, say, four minutes before two o'clock, the air electricity, as it is called, may be turned on, the piston, the air being compressed, is then allowed to escape, and the ball, falling, is sent down the shaft to the London Bridge, travelling; and a similar mechanism is in the Strand. The ball, falling four times in a day, is thus able to give a time to every part of the town.

The daily time is thus kept on the River Thames, and emitted; though the ball only goes down to Hammersmith, a large part of the town is dependent on the wire for the time, as many streets are but a few feet above the level of the Thames; as it is six feet in diameter, exhibits bright colours, and falls through a considerable space, its descent can be seen for a great distance on all sides; and all who choose to regulate their clocks and watches are thus able to accomplish it. The time of the day is sent down the Strand from four to nine o'clock, and from nine to four o'clock. In order to give the time to the ladies, the wire is continued down the street. By the use of the electric telegraph the time can be set to the electric telegraph office, and the time thus set is passed down the wire to the Strand. It is capable of being set in the Strand, and from there it is passed down the street, and by the use of the wire the time is sent to the ladies.
apparatus for drawing up the wires to the proper degree of tightness, and joining the several lengths together. The great number of wires which we see along the chief lines of railway are not all necessary for transmitting one message; a single wire will effect this; but many are required to keep up correspondence of different kinds, and with various stations.

The 'needle telegraph,' as it is called, is still the one generally used in this country; that is, one in which, instead of pressing down the keys of a finger-board, the manipulator works a needle with which he indicates the letters and numbers, the relative positions of which indicate letters and words. The action of the machines was sufficiently described in our former article. [Telegraphis, Elec.;] Improvements have been since introduced, but the principle is in its general features such as Morse and Cooke and Wheaton made it many years ago. The Electric Company have purchased many patented inventions and machines, to be used subsidiary to the needle-telegraph.

Much as there has been of litigation in England concerning electrical telegraphs and inventions, it bears no comparison with that of the United States, where the system is developed with so much more completeness. The telegraphs principally employed in that country are those of Morse, Bain, and House; and it is chiefly the owners of Morse's patent who have secured the greater rights from the government and settlers. The dots and lines of his alphabet; the passing of one or more points, alternately over the paper and over the holes in the paper, broke and re-made the galvanised circuit with great rapidity; and in order to aid the work, Mr. Bain invented an ingenious machine for punching the holes in the paper. The actual transmission was very rapid; but by the time the punching and the subsequent translation into English were completed, not much time was gained over the ordinary methods.

In relation to the wires linking Great Britain with other countries, the submarine principle has been brought very remarkably into operation. Beginning at the north, and working half round the island, we first meet with the Portpatrick and Carrickfergus cable (24 miles) dipping between the North of Ireland and Scotland, and connecting Scotland with Ireland. At one end it joins the submarine cable from Portpatrick through Stranraer to Ayr and the centre of Scotland; the other through Stranraer to Dumfries and the network of British lines. At the other end the cable is connected with various Continental systems.

Without any difficulty a message is sent from London to Ireland via Dumbries without regard to circuitousness of route; for the electric current runs little distance. Next comes the Holyhead and Dublin cable (64 miles), joined at one end to Great Britain and at the other end to one of the Irish lines. In the south is the Hants and Isle of Wight cable, not very important commercially, but establishing electric communication with her Majesty's marine residence at Osborne; it is connected at Hurst Castle through a land-wire running through Yarmouth to Osborne. Farther east is the Dover and Calais cable (28 miles), connected at the two ends with the systems of France and Belgium respectively. Another is the Dover and Ostend cable, connecting England with the Belgian and European wires generally.

Lastly, there is the Orfordness and Hagne cable, joined at one end to a land-wire running to the Ipswich station, and connected with the Dutch land system at Den Hurn station, and at the other end with a land-wire passing through Yarmouth to Osborne. Farther east is the Dover and Calais cable (28 miles), connected at the two ends with the systems of France and Belgium respectively. Another is the Dover and Ostend cable, connecting England with the Belgian and European wires generally.

Directing attention next to the continent of Europe, we find telegraphic wires radiating in all directions. Nations were never more struck with the wonders of the electrical telegraph than on the occasion of the death of the Czar Nicholas in 1855. On the 2nd of March the Earl of Clarendon announced in the House of Lords that the Czar had expired. The news travelled from St. Petersburg to Paris and Berlin, and lain in four days, by means of the actual electric current. Other distinct messages had been received, one from Berlin and the Hague, the other via Berlin and Ostend, both communicating a message telegraphed to Berlin from St. Petersburg, and all in four days, by means of the actual telegraphic current. The dreary wastes of Russia have been brought within the civilising influence of the bit of copper wire, and lines in all directions have been laid, with or without regard to railways. Nearly all the chief cities in Europe are now linked together. Circuits, as is the case from London to Trieste, going through Belgium, Prussia, several minor German States, Saxony,
Bohemia, Austria, and Istria, the connection is nevertheless complete; and telegrams are twice a month transmitted to us relating to Indian affairs, brought to Trieste from Alexandria. Italy, in railways and in telegraphs, is as far in advance of Austria as it is lower than that of Italy. Turkey, to the great astonishment of many of the Osmanlis, has been made a sharer in the fast-going, high-pressure operations of the age: she possesses an electric telegraph, extending from the Black Sea to Trieste; and, according to the most recent messages, will now be finished from London to the seat of the Ottoman empire. During the Russo-Turkish war, an electric cable 300 miles in length was sunk in the Black Sea from Varna in Bulgaria to Kamiesch in the Crimea, there to be available to the Osmanlis engaged in the Mediterranean, and especially in Sebastopol: it was one of the many contributions of peaceful industry to dread war. The Czar Alexander and the Sultan Abdu-l-Medjid, now that hostilities have ceased between them, might, if they did not exchange for telegraphs, for there is an uninterrupted copper wire extending all the way from the capital of the one to that of the other, passing in its route through Berlin, Dresden, and Vienna. Nay, if business or pleasure suggested it, a dozen emperors and kings, seated in a dozen capitals, might exchange greetings all in one day, or perhaps in an hour or two, and might make a score of petty princes sharers in the achievement.

We pass now to the routes for traversing the Mediterranean by telegraph. The two islands of Corsica and Sardinia, belonging to two energetic sovereigns, have been connected by telegraph with the French and Sardinian colonial dominions: land-wires on the islands themselves, and submarine cables to Corsica and from Corsica to France. This being done—how is it to span the broad Mediterranean, so as to connect Europe with regions far beyond? Glancing at a map, we see that the southern end of Sardinia makes a tolerably near approach to the northern coast of Africa, at a point in the pachalic of Tunis. We also see that Sicily, Malta, the Ionian Islands, and Candia, form spots of dry land which might be used as resting places for separate lengths of submarine cable, should commercial and other reasons justify the adoption of such plan. A cable laid by the Sardinian Government, which has been formed, which has laid down a submarine cable on the first of these two routes. From Sardinia to Malta, and from Malta to Corfu, it was found that the water is of much less depth than in the line of route from Sardinia to Africa; and as these islands lie in the way towards the Levant and Egypt, an enterprising company was engaged to connect the various islands by a chain of telegraphic links. The whole of this line, 450 miles from Sardinia to Malta, and 350 miles from Malta to Corfu, has been completed. The next project; the part of the Austrian Government to extend their telegraph from Tripoli to Tunis, to lay down a submarine cable from Tunis to Corfu, there to join the line just described, and thence to extend it to Alexandria, with or without the Ionian Islands. The intermediate Mediterranean cables, actual or proposed, may thus be classed in four groups: from Spezzia in the Genoese State to Cagliari in Sardinia, promoted and supported by the Sardinian Government; from Cagliari to Africa, by the French Government; from Cagliari to Malta and Corfu, by the English Government; and from Tripoli to Corfu and Alexandria, by the Austrian Government.

Next, a few words must be said concerning the rival projects for connecting Asia with Europe by telegraph. Supposing all the attempts in the Mediterranean to succeed (and succeed they probably will after a time), there will be one terminus of electro-communication on the north coast of Africa, another at Corfu, and a third at Constantinople; and the question then arises, to what place in the system of telegraphy in Asia. Two projects have been competing for public favour during 1857 and 1858—the Red Sea and the Euphrates routes. The first of these comprises a submerged cable along the Red Sea, which is supposed to be laid with a British or a French, or a submarine cable to India; while the other starts from Syria or from Asia Minor, and follows the valleys of the Euphrates through Mesopotamia to the Persian Gulf and the Indian Ocean. The choice of the road depends on the merit of the one or the other; but a look at the map will show that it is of little consequence in the way. There would be a land line of 340 miles from Alexandria to Suez; and then a submerged cable of 4200 miles from Suez to Kurrachee in India in two lengths, joined at Aden as a resting-point.

Between Suez and Aden there would be three resting-points on land, at Cosseir, Juddah, and Camaran; while there would be three others between Aden and Kurrachee, at Ras Shurra-the, the Kocha Mountains Island, and at Ras el Had, in the Iram of Muscat's territory. The promoters say that 700,000l. in money, and one year in time, would complete this great enterprise; but that if the Indian Ocean section, from Aden to Kurrachee, were suspended for two years, the cable to Kurrachee could be completed for 300,000l., in money, and eight months of time, would suffice to establish a telegraph from Alexandria to Aden. The promoters urge that they have obtained the necessary firmans from the Turkish and Egyptian Governments; that a cable has been laid from the districts of territory; that plans are already made by other parties to connect Alexandria with Europe by a cable from Austrian and Sardinian ports; and that, even should these projects fail, the value of the Telegraph Company's wire from Corfu to lay down a cable of 800 miles from Alexandria to Constantinople—in either case ensuring complete telegraphic communication from London to India. On the other hand, the Euphrates Company proposes a land-wire of 1200 miles, starting from Constantinople, stretching south-eastwards across Asia Minor, and thence to the Euphrates, or to Baghdad on the Tigris; then a river-cable to the Persian Gulf, and lastly, a submarine cable to Kurrachee at the mouth of the Indus—the two cables together being about 1600 miles, or 2500 miles as a whole, from Corfu to Kurrachee. The estimated cost is 400,000l., and the time of completion six or eight months.

Having thus noticed the various projects for establishing electro-telegraphic communication between Europe and India, we will consider what has been effected in India. In 1852 Dr. O'Shaughnessy, after a series of preliminary experiments, was empowered by the East India Company to establish a magnificent series of telegraphs in that country. During the remainder of that year, and the whole of 1853, he was employed in procuring from England the immense quantity of material required, and all the working apparatus. He commenced the actual construction shortly before the end of the year just named, and on the 24th of March, 1854, he established a line from Calcutta to Durngapore, in the province of Arcot. Proceeding energetically with his labours, Dr. O'Shaughnessy was able to announce that, on the 1st of February, 1855, only about fourteen months after his commencement, he had completed the whole trunk line from Calcutta through Agra, Delhi, and Lahore; to stock on the Indus; a branch from Agra to Bombay; and another from Bombay to Madras—the whole extending to 3050 miles, and including 41 offices or telegraph stations. During the year 1856 the communications were extended to include Attck to Peshawur on the Afghan frontier, from Rangoon to Meeaday on the Burmese frontier, and from Bangalore to Ootacamund—extending the total length to 4000 miles. During 1856, and so much of 1857 as was uninterrupted by the war, the whole line was completed, and is now extended to more than 5000 miles. Throughout Central India the engineer was opposed by enormous difficulties; there was no metalized road; there were few bridges; the jungles are in many places deadly for at least half the year; and there was no police for the protection of the wires. More than seventy principal rivers have been crossed, some by cables, others by wires extended between masts; the Tombuddra crossing was two miles wide, and that of the Soane more than three miles. The greatest difficulty of the whole was the crossing of the Indus. Madras the telegraph is more substantial than any known in Europe or America; for 174 miles the wire is borne on masonry pillars capped with granite; while for 333 miles it is supported on superb granite slabs, each 16 feet high. The whole expense has, nevertheless, been kept within 60l. per mile.

Viewing the state of telegraphy on the other side of the Atlantic, we come to that which almost baffles calculation. The long wire in Europe is a thing of the past. Telegraphs are now laid in all directions, but the telegraphic wires have far outstripped them in length. The Americans, having millions of acres that belong to no one, or that are of very slight value, set up their telegraphic poles and stretch their wires in spots where no one ever thought to lay a line. The provisions of the Telegraph Act of 1851, though they have been much increased and extended through forests, over rivers, across prairies, over mountains—nothing stops them, and as the engineers and companies care little about strength or symmetry, the telegraphs are set up with wonderful cheapness. Cheaperness of telegraph leads
Atlantic Telegraph.—The effort to establish a telegraphic communication between England and the United States so far transcends every previous undertaking of the kind that we deem it advisable to describe the operations in some detail. The American government under the circumstances with which we have been favoured by a gentleman intimately acquainted with the whole course of the proceedings.

A company having been formed in 1856 for the purpose of connecting the two countries by a line of electric telegraph, under the authority of two acts of Congress, with the requisite capital having been subscribed, the Governments of Great Britain and the United States agreed not only to pay each to the Company a subsidy of 10,000£ a year, for 25 years, but to assist the undertaking, by furnishing the men and ships which should be required in the laying of the cable. The preparation and perfection of the electrical details of the work were left in the hands of Mr. Wildman Whitehouse.

Three gentleman who had practical experience in the work of marine telegraphy, Mr. Canning, who submiered the Newfoundland cable, Mr. Woodhouse, who connected Balaklava and Varna during the Russian war, and Mr. F. C. Webb, who had the charge of the line between Orfordness and the Hague, were associated with Mr. C. Bright, in preparing the cable. In 1856 he was enabled to operate at Greenock, the manufacture of the paying out machinery being intrusted to Mr. Henry Clifford, under the superintendence of Mr. C. Bright. A company which had been incorporated for the purpose of manufacturing electrical apparatus, and known as the “New York, Newfoundland, and London Telegraph Company,” transferred all their rights to the Atlantic Company, securing to them the exclusive privilege of landing a cable upon the Newfoundland shores during fifty years, and upon the coasts of Nova Scotia during twenty-five years. Patent rights in apparatus which would be required in working the line, were also secured to the company by Messrs. Whitehouse and Bright.

Before the actual operations of the undertaking were entered upon, it was found of utmost importance that the capability of transmitting an electrical current through a coated conducting wire as long as the Atlantic is wide, should be put to the test of direct experiments. Mr. Whitehouse had already availed himself of several opportunities furnished by the chance of lengths of cable being under construction, which had separate wires imbedded in the insulated gutta percha mass; the wires being so joined at their extremities upon the occasion of the experiments as to form continuous lines of conduction. In 1856 he was enabled to operate at Greenock, with an extent of 1146 miles. In the following year, with the co-operation of the Magnetic Telegraph Company, arrangements were made for the crowing trial in the presence of Professor Morse, he challenging to be in England at the time and company in the undertaking. The line was laid, and through the sea, from London through Dumbries to Dublin, along a course of 660 miles. They are also so numerous, and so connected with a wide system of ramifications, that, upon need, a length of some six thousand miles can be harnessed. Upon a pre-determined night, that of the 9th of October, ten gutta-percha-covered insulated wires, each more than 2000 miles long, were connected into a continuous circuit of more than 2000 miles. The conclusive of experimentalists met at the telegraph company's offices and, in presence of a pair of Mr. Whitehouse's induction-coils were used to excite the wires, and the current was made to act through one of Professor Morse's ordinary recording instruments. Signals were distinctly telegraphed through the two thousand miles of wire, and received at $10, 241, and 270 per minute! This result was deemed eminently successful, and as proving beyond all fair ground of question, that the transmission of an electric signal through a coated wire laid across the bed of the Atlantic or other large bodies of water, is not only possible, but feasible, for though the greater part of the cable employed in this experiment was subterranean rather than subaqueous, it is now well known to the initiated in these matters, that the two cases are, as nearly as possible, identical in all their essential characteristics.

During the preparation for the construction of the Atlantic cable, and indeed even more available during its manufacture, Mr. Whitehouse was engaged in putting several important matters concerning the rationale of electrical action to the rigid questioning of experiment. Many of the results which were elicited through these investigations are of surpassing interest, and require to be alluded to as constituting notable passages to the pages of the history of electrical science. Foremost among the labourers of the experimentalist, however, necessarily stood the completion of his instrumental means of research. He very soon found that the instruments which had been previously in use as measures of electrical intensity and tension were insufficient for the examinations he had entered upon. He consequently set himself to work seriously to remedy the defect.

The usual method whereby the force of an electrical current is determined, is to produce, by its influence, a magnetic needle placed on a freely suspended needle near to, or within, a many spared coil of the conducting wire. The degree of the magnetic needle’s deflection from its position of equilibrium, was then held to give the acting force of the current. This answered very well so long as only continuous currents of moderate intensity were under examination. When, however, the experimentalist came to deal with sudden and interrupted currents of high intensity, such as the streams are which the Atlantic telegraphists have to deal with, no steady deflection could be produced. The needle jerked fitfully and violently backwards and forwards with so much caprice that it defied the adroitness of the most skilful observer to get any intelligible indication of force out of its position.

This was necessarily the result of the insufficiency to disperse altogether in his investigations with the fibul and unstable needle, and to call in to his assistance, in its stead, that power which is fixed and stable beyond all other forces that are known to man. He resolved that he would avail himself of the magnetic needle, and that he would put its strength in the scale, make terrestrial gravity determine the amount, and send in a record of the same in grams. The ingenious piece of apparatus whereby he accomplished this curious feat of weighing electrical power, Mr. Whitehouse designed; and when he prepared the mechanical details of its construction, his Magneto-Electrometer.

Mr. Whitehouse’s instrument for measuring the force of electrical currents is a kind of a dash pendulum suspended at each side by springs similar to those which are used for the support of the pendulums of clocks. The short end of the steel-yard is armed with a bar of soft iron, and at a short distance beneath this is placed another bar of soft iron, surrounded by a coil of fine silk-covered copper wire, and therefore capable of being converted into a magnet whenever a current of electricity is flowing through the coil. The strength of the artificially formed magnet depends on the power of the current which flows through the coil, and consequently on the extent of the deflection of the pendulum when the long arm of the steel-yard accordingly as the short arm is more or less powerfully attracted. By shifting weights along the steel-yard, by changing these weights for others of different magnitude, and placing them at different distances from the artificially magnetised bar, so wide a range of mechanical adjustment is commanded that degrees of attraction can be accurately estimated from those capable of tilting up but a small fractional part of a grain, to those which can lift many thousands of grains.

Mr. Whitehouse also prepared an instrument which enabled him to compare the velocity of transmission of different currents of electricity through the same wire, or of the same current through different wires. This instrument consists of a single line of galvanism, which supplies a voltaic battery, and of a ribbon of chemically prepared paper unrolled from a drum by a train of clock-work. The pendulum hangs upon a pivot, which is vertically one of the poles of the volatice battery, and its rod is prolonged upwards into a sort of crest, which comes into contact with a spring right and left, as it swings to and fro. The springs, when not touched by the pendulum, press upon a metallic pillar, which is itself the other pole of the voltaic battery. The pendulum is in the form of a cross, having four different things for the time, from the pillar. When it lifts the left spring exactly the opposite proceeding occurs. The wire which forms the circuit, and which is supposed to be a lengthened one, is curled into a coil near to either extremity, and into each of those coils a bar of soft iron is inserted. These bars become temporary
magnets whenever a current of electricity is passing through the coils, but the precise polarity of either extremity depends on the way the current passes. The extremity, which is a north pole when the current issues from the battery through the right spring of the pendulum apparatus, becomes a south pole when the current issues through the left spring. Near to each temporary magnet is placed a permanent magnetic magnet, traveling upon a central pivot, in such a way that it can be acted upon and made to traverse backwards and forwards by the reversal of the temporary magnetism. Now when these traversing magnets lie in one position they make a contact, and turn on each a small local voltaic battery in connection with its magnets. Its polarisation is in the same way, and can be estimated by comparison with the second's long trace, will afford a measure of the time. In this way the length of time the electrical current takes to run through the wire from one printing instrument to the other, can be determined with precision, and also the fraction of the second, which is the linear representative of a second. It does not at all matter what the speed is with which the paper ribbon is unwound beneath the printing style, because the estimate is always a relative one referred at each instant to a particular track made by the printing action. When the pendulum is traversing transmission in any special wire is to be examined, the apparatus is set to work, and a somewhat lengthened series of observations of printed matter is the result, which is thus slowly scrutinised, the secret of the precise recording is rejected, and the mean of all the more trustworthy ones noted as the result to be adopted.

One of the most important deductions arrived at through the instrumentality of this ingenious apparatus, was the fact that voltaic electricity is capable of producing greater mechanical effects at the extremity of any given wire, than the induced electro-magnetic current, but performs its journey through a long coil with inferior speed to its weaker companion. As is commonly the case in other matters, the subsidiary affects of the journey are much greater by the most direct than by the most indirect. Seventy-two pairs of sixteen-inch sand-battery plates lifted 1400 grains on the steel-yard of the magneto-eleetrometer at the end of 800 miles wire, but the current on the west of London was found by Mr. Whitehouse to be only 640 at the distance. Two large electro-magnetic induction coils, excited by a Smees's battery of ten pairs of one hundred square-inch plates, sent forth a current which lifted only 745 grains at the end of the same wire, but which arrived at that end in nineteen hundredth of a second. Simple voltaic electricity is capable of greater mechanical effect, under any given arrangement of conductors, than an induced electro-magnetic current, but the electro-magnetic current through lengthened conductors with a considerably superior velocity to the electricity of the same intensity born forth from induction-coils possesses a treble velocity of transmission, and realises consequently a three-fold working speed as compared with simple voltaic electricity. It was hence obvious that induced, and not voltaic electricity, must be adopted for the wide Atlantic service, where the ultimate commercial success of the enterprise would be mainly dependent upon the number of signals which could be forwarded in any given time.

In my early experiments made to determine the rate of movement of the electrical influence along telegraph-wires, it appeared that it could pass through hundreds of thousands of miles in a single second of time. When however a steady wire was arranged, and was actuated upon with telegraph-wires coated with gutta-percha, it could be proved that the movement of the electric influence through this wire, and through the sea, instead of being freely suspended in the air, it seemed that scarcely thousands of miles were traversed in a second. Different experiments, too, arrived at different results for the rate of speed. In a paper read by Mr. Edward Bright, at the meeting of the British Association in 1834, the statement was made that the velocity of currents in ordinary submarine lines did not exceed one thousand miles per second; this gentleman had also inferred from experiments made in a circuit of 480 miles underground, that the speed of the electric impulse varied with the energy or intensity of the current, and with the nature of the conductor and conditions in which it was placed. When Mr. Whitehouse turned his attention to this question, his investigations amply confirmed the deduction which had been previously drawn. Working with his pendulum-apparatus he found that the mean or true velocity of the electric current in the copper wire, is about 1400 miles per second. But he also ascertained that that of the induced electro-magnetic current is 4300 miles per second. He determined too that the speed of the voltaic current might be raised under especial circumstances to 1600 miles per second, and that of the induced current might be augmented to 6000 miles per second.

But what could be the cause of these varying rates of speed, and of the extraordinary interval which the electrical influence was thus proved to suffer when it was constrained to traverse covered underground or sub-marine wires, instead of air-surrounding conductors? Professor Faraday had thoroughly investigated this question so soon as the usefulness of the apparatus had been at all confirmed, by a series of experiments which caused the most extraordinary and arresting phenomena, but which, however, the wires are inclosed in a compact sheath of insulating substance, like gutta-percha, and are placed in water or moist earth, the affair is altogether changed. A new agent then comes into play, and this is moisture, and any other substance, which, however slightly excited, the electrical experiment operates upon the near at hand outer layer of moisture, and it being a conductor, calls up in it an electrical excitation of an opposite kind. The two electrical forces then pull against each other, and so much the more, the more the insulating sheath, and hold, each the other, fast locked. The inner excited influence keeps the outer reduced force stationary upon the external surface of the insulating sheath. The outer induced force keeps a certain portion of the inner influence in the sheath as a charge, and so prevents it from moving as freely onward upon its journey as it otherwise would. The submarine telegraph cable is indeed virtually a lengthened out Leyden jar, and is necessarily charged with a certain measure of electricity when it is in use. It is a reservoir or bottle for the electricity, which has to be filled and emptied, as well as a channel or pipe through which the influence may be poured. When an extent of water has been deprived of its charge, it may be filled again by a more or less capacious bottle in virtue of its length, however narrow its transverse dimensions may be. In the more ordinary practice of artificially induced electricity, the voltaic current is not able to produce a static charge in a Leyden jar. In the case of the coated wire of the electric telegraph it is able to do so, probably in consequence of the comparatively enormous extent of surface which comes to be concerned. Now it is this peculiarity of the action of the coated telegraph-wire which leads to the slower rate at which the electric influence is transmitted through the main substance of wire. A certain amount of water, that is there, must be filled to satiety with the force before any transmission can be effected, and then must be emptied completely before any new transmission can be made. Mr. Whitehouse was able by delicate instruments to procure a very beautiful illustrative proof that it is a charged Leyden jar, and not simply as conductors, that submarine cables, or subterranean coated wires act. He took fifteen miles of the Atlantic cable, consisting of an internal conducting strand, with its protecting silver-coated envelope, or insulating sheath, and he turned up the further end into the air, thus leaving the conducting wire entirely insulated that way. He next took 200 miles of the same cable, and arranged it in precisely the same fashion. He now found that he could charge each of these cable specimens, and then make the charges to remain for a few seconds in the wire, and then discharge them back through the nearer end, measuring the force of the discharge, and therefore the amount of influence which had been indirectly retained in the wires, by the
magnetic-electrometer as it flowed out under a constrant
which forced it to pass through the coil. The discharge
from the 12-mile length of the wire lifted 1076 grains on
the steel-yard of the electrometer. The discharge from
the 200-miles length lifted 2300 grains. A current which
lifted 18,000 grains upon being simply poured through
the coil of the electrometer, lifted 60,000 grains when allowed
to flow at the end at which it had received the power
charge, and had produced the most powerful effects. If the wires
had been worked at a lower tension, the effect produced would
necessarily have produced the weaker and not the stronger
effect, on account of the electrical influence being attentuated
through its greater extent.

Most electricians had held, previously to the period of Mr.
Whitehouse's investigations, that the available force of an
electric current is diminished by increasing distance, or in
other words by the length of the transmitting medium, in
the rates of the square of the distance it has traversed. It
was very important that a conductor should receive imme-
diate and full investigation, because, if the received dogmas
were true, it was obvious that the difficulty must be very
great indeed, of getting any efficient current to present itself
on the opposite shore of the Atlantic, it having been started
from the American coast, which in itself would be strong enough to produce very decided results at
the distance of 500 miles, would be rendered at this
greater distance almost evanescent. Mr. Whitehouse accord-
ingly proceeded to test the deduction in two ways. First,
by employing at the end of the cable, a positive electrometer,
for determining the mechanical effects in consequence of its having made certain extended journeys; and then by closely scrutinizing its loss of
speed at varying distances. The current from a voltaic
battery, consisting of 72 cells of 6-inch lantern, was trans-
mitted through 4 cables, each consisting of 360 wires of
different lengths. Where the wire was only a few feet long, 20,000
grains were lifted on the electrometer. With a wire 300 miles
long, 10,650 grains were lifted. With 400 miles, 32,650 grains,
and with 600 miles, 75,600 grains. Similar experiments were made with wires ranging from 80 to 1020 miles
long, to determine the rate of transmission. With a length
of wire of 83 miles, the transmission was accomplished in
eight-hundredths of a second. With 168 miles in fourteen-
hundredths of a second. With 248 miles in thirty-six-hun-
dredths of a second. With 498 miles in seventy-nine hun-
dredths of a second, and with 1092 miles in a trifle less than
a second and a half. Taking 83 miles as the unit in these
results, there was a very decided acceleration by applying
numbers of wires. To this, if the so-called law of the
squares of the distances were correct, the transmis-
sion through the 1092 miles of wire ought to have required
144 times as long as the transmission through the 83
miles, which was not the case. The experiments were
employed in the distances represented by the series 1, 2, and
3, the rates of velocity were represented by the fractional
series ½, ⅓. It therefore appears, from experiments, that
nature is more suspicious to the cause of wide ocean telegra-
phy, than the assumption of theory.

During the experimental investigations of this portion of
the subject, a very surprising and an altogether unforeseen
result was obtained. In the attempt to ascertain how small
a quantity-battery would prove sufficient to effect a charge
and a discharge in the Atlantic, an Atlantic cable, Mr.
Whitehouse had a piece of apparatus prepared consisting of
taxi-five pairs of zinc and silver plates, each about the twentieth of a square inch large, and the pairs so arranged that they could hold a drop of acridulated
water between them. On charging this illiputian
battery, by dipping the plates into salt and water, messages
were sent from it through the thousand miles of cable with
the utmost ease; and not only so. Pair after pair was
dropped into the solution, and the message was repeated,
equal facility, until at last only a single pair, charged by one
small drop of liquid was needed. Strange to say, with this
single pair, and single drop, distinct signals were effected
through the thousand miles of the cable. Such signals were
repeated at the rate of 72 words a minute. The reduction of the
time of 1000 miles to less than 30 seconds of time. This remarkable experiment demonstrated how slight a current might be made to give very good results,
when a conductor as perfectly insulated as the copper strand
of the Atlantic cable was made the channel of transmission.

In some of Mr. Whitehouse's early experiments it was
found that the induced electro-magnetic current took a second
and a half to discharge in half, when it moved through a coated
wire 1146 miles long in consequence of the reducing in-
sence of induction in this lengthened channel. This appa-
rently is a very excellent result—a signal conveyed eleven
hundred miles in less than two seconds! It is not enough,
however, for the important service of Atlantic telegraphy.
In spelling out messages, most letters require the use of
sounds each, consequently with this rate of transmission it would
be extremely difficult to send enough words across the Atlantic
within twenty-four hours, to enable the company to work
in the public interest, and to permit the Atlantic submarine
experimenter, therefore, set himself to see whether he could
not find some means of quickening the pace of his too lag-
ging messenger. He ultimately accomplished his object by
means of an arrangement with electro-magnetic coils which
enabled the operator, through the simple reversal of the
poles of the magnet to send currents of different kinds of electricity,
one after the other through the conducting wire. Each suc-
cessive transmission then served to clear away the lagging
envelope of the antagonist current, which immediately pre-
ceded it. The remains of the old current which clung
about the wire pertinaciously, were completely and rapidly put
to the rout upon the stream of an opposite kind being thrown in.
When positive followed negative, and negative followed post-
itive, a current of decided positive force was always
secured. The wire was continually restored as fast as it was
disturbed, and its telegraphic capabilities were in this way
steadily maintained. By the use of these altereded electrical
currents, seven and eight signals were now distinctly recorded
through the same wire in a second, instead of one signal in a second and a half.

When the idea was first entertained that electrical cur-
rents would run along coated telegraph-wires with a velocity
that was inversely proportional to the square of the dis-
tances traversed, it was thought that the difficulty might be
partially overcome by providing them a wider road to travel
along. It was conceived, that if one of two wires of equal
length, was six times as large as the other, that wire ought
to transmit its messages with a velocity three times greater
facility and rate of speed. Hence it was proposed that
long wires should always be made larger than short ones.
But this proposal became a matter of very great consequence
when a cable of sufficient length to span the Atlantic was
concerned. A cable possessed of the Dover and Calais one, if extended enough for the Atlantic
service would weigh not less than 20,000 tons. But if the
Dover and Calais cable were only duly proportioned to its
work, the Atlantic cable would be required, by theory, to be
considerably larger and heavier. It could not be a
16-mile vessel as the Leviathan would be capacious enough to carry
more than a small part of it. The weight, too, that would
be dependent upon itself and upon the stern of the vessel
from which it was to be employed. This weight, it was
found, amounted to a considerable number of tons. Mr. Whitehouse,
consequently, applied himself with considerable anxiety to
determine how far this view was based in fact. He worked
with a 300 miles length of cable which had three insulated
wires running along parallel to each other, but distinct,
through one mass of guita-percha, so that he could use a
single wire, or a double, or a treble one, at will, combined as
one. Some 300 separate observations were made, and to the
experimenter's great relief it proved, that the wire of in-
creased capacity, transmitted its electric currents in a
facility and speed than the smaller one. With a length of 166
miles the velocity of the induced electro-magnetic current was
eight-hundredths of a second in a single wire. With the double
wire it was nine hundredths; and with the trebled wire it
was nine and a half hundredths. Increasing the size of the
conductor actually augmented the retardation of the electrical transmission through it. All Mr. Whitehouse's experiments
taken together seemed to warrant the conclusion, that a tre-
bleded cable would be considerably retarding.

When the actual construction of the Atlantic telegraph-
cable was commenced, certain important facts had therefore
been determined which served as very excellent indications of
the principles upon which the manufacture of the apparatus
would have to be done. It was found that the guita-percha covered submarine wires transmit the agent entrusted
to their conveyance as induction-immenbered Leyden jars,
and that consequently the transmission is effected with
a velocity which is modified and influenced by external

Digitized by Google
conditions. Also that induced electro-magnetic currents of a certain determinate intensity, travel more quickly than simple voltaic currents, and that the rapidity with which signals are transmitted by the agency of electro-magnetic currents, can be greatly increased by using opposite electro-magnetic currents, either electrically, or without being electrically, by using one conductor alternately. It was also clear that the diminution of the speed of movement among induction-embarassed wires was not in so high a ratio as the squares of the distances traversed; that several distinct waves of transmission might be made to run along the same wire, so that the largest currents through large coated wires transmitted with less facility and freedom than small ones, in consequence of requiring a larger charge to saturate their inductive capacities before they were in a fit state to transmit; and that therefore the facility of transmission of the greatest movement in wide ocean telegraphy; and that by the use of small wires, very perfectly insulated, and of electro-magnetic induction-coils of powers carefully apportioned to the dimensions of the wires, signals might be transmitted through a distance of 2000 miles with a rapidity amply sufficient for all purposes of revenue to the Company and of utility to commerce.

It was necessary, then, that an Atlantic cable, which was to furnish a fair promise of success, should have a well insulated and conducting core, and a certain moderate speed of movement, so that it should be so light as to be easily conveyed across the Atlantic, and easily handled during paying out, and yet be so dense as to be able to sink with facility to the depths of the Atlantic, and so strong that it could resist any strain to which it might be subjected while in transiton. It was also essential that it should be so flexible that it could be readily coiled up in the store-spaces of the factories, and of the vessels employed in paying out, and rolled over the sheaves of the paying-out alleys, and yet possessing sufficient inertia and rigidity to allow of its lying in a tolerably straight line when once in situ at the bottom of the sea.

The following is the plan which, in accordance with the indications of these multiplied experiments, was finally adopted. A cable made of the seven wires of the purest copper of the No. 22 gauge, was first prepared, it being the sixteenth of an inch in diameter when twisted. The strand of seven wires was adopted in preference to a single wire of the same practical capacity, because the probability of a destruction of continuity was in this way greatly diminished. In case of any accident occurring it was very unlikely that all the seven wires would be broken in exactly the same place, and so long as only one of them remained sound, the electrical transmission could be carried on. The strand itself was subject to a strain which stretched it twenty per cent., without any appreciable injury to its conducting power being discovered. To show that no amount of alteration, which could possibly be produced by accident, could possibly have any influence upon its insulating utility as a telegraphic conductor, one mile of wire eleven times smaller than the strand, was introduced into a gap made in a 600-mile length of the cable, and the effect produced was seen. The transmission of messages after the alteration was tested. It proved that the transmitting capacity of the cable was only diminished by one thirty-seventh part.

As the copper strand was prepared, it was rolled upon drums, and then taken from the drums to have three separate coatings of gutta percha applied, until the aggregate diameter was thus brought up to about three-eighths of an inch. The gutta percha used for these coatings was prepared with the utmost possible care. It was first rapped into shreds, and was afterwards heated and melted through several layers of fine wire gauze, and kneaded for hours in the presence of steam by steam machinery. It was then briefly squeezed through very fine screws, through dyes, as the strand of copper was gradually drawn along between them, and so made to adapt itself as a compact sheath to the strand. The several clear coatings were given to the strand in order that any imperfection left in the first might be compensated and remedied by the next coat applied. The completed core was subjected to a pressure of five tons upon the square inch, by the use of hydraulic presses, and thus became the insulating material being at all injured by the force applied.

During the process of the manufacture of this core it was submitted to constant examination to prove both that the copper strand continued unimpaired, and also that the insulating power of the gutta percha was as complete as it was required to be. The continuity was proved by passing a voltaic current of low intensity from a battery of a single pair of plates, through the strand, and then causin it to record a signal after leaving the wire. A battery of low intensity was employed for this purpose, because it made the test so much the more severe. A strong battery might have thrown the current through a slight imperfection in the gutta percha, which might not have been able to overcome. The due perfection of the insulation was tried by turning up into the air the end of the length of core about to be examined, and by then connecting one pole of a voltaic battery of five hundred pairs of plates with the strands, and the other pole with the earth. At the same time, a copper wire was run through the earth, a magnetic galvanometer being suspended within a coil continuous with the strand. So long as the insulation of the strand was fairly perfect, the copper wires became charged with a very small current, no current passing through the wire, no current was produced through the strand, and no deflection of any consequence appeared in the magnetic needle. When the insulating sheath, on the other hand, was imperfect, the electrical charge leaked through the imperfectness of the sheath, and so back to the opposite pole of the battery. In this way a current was set up in the wire to supply the leakage, and the magnetic needle was deflected from its position of equilibrum, the deflection being in proportion to the amount of the current. A strong deflection, therefore, would prove a sharp imperfection in the gutta percha, which would force a passage through an imperfectness which might be too slight to allow a weak current to make its way. During the progressive examination, every precaution was taken to protect the gutta percha, a low tension was also introduced into the circuit of the ring, so that its current flowed round continually, from pole to pole, through the strand. An insulated bell was also placed in the circuit, that any break of continuity might be instantly detected, and the bell would sound. Another bell instrument was so arranged that it was rung whenever the current from the five hundred cell battery began to run, in consequence of electrical leakage, with undesirable speed. The feeble battery in the circuit ran its bell whenever the circuit was broken. The strong battery out of the circuit rung its bell whenever an onflowing current was set up through the strand, in consequence of the insulating sheath being unable to retain the charge.

The series of experiments the very remarkable discovery was made, that the insulating power of gutta percha is very materially affected by temperature. A high temperature seems greatly to impair its insulating capacity, and the recent experiments performed in the laboratory of Mr. Janvier have only confirmed that statement. The results were confirmed by Captain Dayman of the Cyclope, who have enabled him to determine the deep-sea temperature over a very considerable range, and are abundantly confirmatory of this fact.

The separate lengths of manufactured core were then joined into a single ground wire, and a very strong insulating material being at all injured by the force applied.

aid of hot irons. In case of the core on each side of the joint being at any time so dragged that the ends of the strand were broken asunder, this outer investment of wire would unroll spirally without being detached from the strand. Thus the electric continuity of the strand would be preserved even when the strand itself was severed.

Every two miles of the completed core were wound upon channelled drums with deep flanges, iron shot at the rim, so that they could be rolled about and made to perform their own locomotion. When the contents of these drums were used up, another was substituted. The core, thus twisted and pitched, was attached to the outgoing core of the compressed cable, and so the contents were unrolled from the drum as the external metallic wires were spun round the core. During the process the work is performed by a large pair of large pitch and tar, was compactly wound the core to act as a bed for the external metallic sheath. Then eighteen strands, each of seven wires of charcoal iron, were twisted firmly round the core. The strands and the cable were made by precisely analogous machinery. A large horizontal table, containing seven bobbins on the circumference in the case of the strand machine, and eighteen in the case of the closing or finishing machine, was whirled round by steam power with great rapidity. A central wire, or the core, was drawn up the table by means of a heavy rope, which was invested with a twisted whorl of wires or strands, given off from the bobbins as the table revolved. The strands were used, in completing the cable, instead of solid wires, because by this means every part of the strand was brought into contact with the material used, were obtained. The external investment of iron was solely designed to protect the coated core from mechanical violence during the act of submergence, and to confer upon it a convenient amount of weight for effecting its descent from the surface of the sea.

Each strand-machine, during the manufacture of the cable, was worked day and night, and in twenty-four hours spun ninety-eight miles of wire into fourteen miles of strand. The several strand-machines at work simultaneously spun a cable twenty-three miles in twenty hours and a half, or into 204 miles of strand. As much as thirty miles of cable have been made within twenty-four hours. At one time all the wire-drawers in England proved to be unable to supply the ever-increasing demands of the machinery, and the works had to pass for a short space. The entire length of wire, iron and copper, spun into this wonderful structure, amounts to 3,328,500 miles; a length sufficient to encircle the earth thirteen times! The completed cable weighed from nineteen hundred to two thousand pounds per mile. The quantity of copper used, was a little more than two hundred pounds, and a certain portion of the weight would necessarily be borne by friction against the particles of the water as the rope sunk; it was anticipated that the cable would never, under any circumstances, be required to meet a strain of more than one ton and a half. The Atlantic cable is to be worked at the bottom of the sea by means of electro-magnetic currents called forth by an instrumental agency of a somewhat complicated kind. First and foremost in this agency, as the primary source of the working influence, stands Whitehouse's "Perpetual Maintenance Battery." This battery consists of large plates of platination silver, and amalgamated zinc, mounted in cells of gutta percha. There are several plates, both of silver and zinc, in each cell, and they are separated by a technical bar of mica at the bottom of the cell, and all the silver plates hang upon a similar bar at the top of the cell, so that there is virtually but a single stretch of silver, and a single stretch of zinc in operation. This arrangement is made because it enables any portion of either silver or zinc to be removed for repair or renewal without stopping for a moment the operation of the battery. As any one lamina becomes imperfect, it can be taken out from its groove, and replaced. Each cell contains two thousand square inches of active surface, the amount of current that each can produce is 4,500 milliamps, therefore the total output of the whole battery will be of the magnitude of a thousand million amperes. Since it is a very solid and heavy instrument, it is necessary that all the parts be carefully ventilated in order to prevent accumulation of gas. The temperature of the water where the cable is laid is so high that the battery is very rapidly heated, and the gases thus formed would be dangerous to the life of the animal. The Atlantic cable is supplied with a "drum" which is a very strong metal cylinder, and is used for the purpose of receiving the cable whilst it is laid in its proper position. One end of this cylinder is fixed and serves as a point of support, while the other end is free and can travel. The "drum" is actuated by the temporary magnet. The pole of the permanent magnet is attracted by the south pole of the temporary one, and vice versa; so that as the polarity of the

screws burn with vivid scintillation. These brilliant effects are, however, inconvenient in one particular. They are produced at the expense of the apparatus. The metallic surfaces from which they are emitted, are rapidly burned away during their continuance. In order, as far as possible, to alleviate this injurious effect, the act is made and broken, during the transmission of electrical signals, by means of a key presenting a very large surface of metal. A horizontal bar, flattened at the top, turns backwards and forwards pioetways, and tills its edges against twenty flat brass springs similarly flattened and kept to the same plane by means of washers on each side. A constant slight leak of the current is also continually maintained through a curl of platinum wire placed in water. By this contrivance the injurious force of the electric current is very much diminished.

The cost of maintaining this magnificent ten-ton ship of Industry at work does not exceed a shilling per hour.

But it has been stated that the voltaic current is by no means a fleet message compared with other agents which are in use at the command of the electrician. Consequently it is not the electric stream generated in this mighty battery which is designed to be actually sent across the Atlantic on the performance of telegraphic service. This primary power is only used to call up and stimulate the energy of a more speedy agent to do the actual conveyance. This auxiliary is transmitted to a piece of complicated apparatus known as Mr. Whitehouse's "Double Induction Coils." These coils are arranged in pairs, and each coil consists, first, of a thick metallic tube, coated on the outside of it with a sheet of gutta percha enveloping the bar; next of several miles of comparatively fine silk-covered copper wire, coiled round the gutta percha sheath and bar; and finally of a mile and a half of silk-covered coarser copper wire coiled round outside the inner coil. These wires are employed to make the communication or connection. Now the inside iron bars, here, are intended to be made into temporary magnets by the action of electrical currents circulating through the coils. The outer coil of coarse wire carries the battery-current from the primary generator, and the inner coil, which is produced in a coil, is the primary or generating coil. The inner coil of finer wire has a new independent current set up in it by the instrumentality of the temporary magnet; as the primary current makes a magnet, so the magnet makes a secondary current in the previously quiescent coil, and this secondary and magnetically induced current it is which is sent off brisk enough to perform the work of rushing across the Atlantic. This independent secondary current is therefore the transmission-current on which the mechanical effect which is produced in the telegraphic circuit depends. The proper term for the current which is produced in the coil at the receiving end, and is called the secondary current, by which the telegraphic messages are conveyed, is the "transmission-current." In the Atlantic cable, this transmission-current is rendered harmless by the size and extent of the cable, and its success has been so complete that it has been necessary to add to the original cable a second, called the "return-line" wire, and to use a "drum" to wind the wires on as they are laid on the bottom of the sea.
The temporary magnet is reversed, the permanent magnet is caused to traverse. When it traverses one way, it opens the outlet of the local battery by effecting a contact and causes it to print; when it traverses the other way it shuts off the current of the local battery, so that it is constrained to keep itself reversed.

It is the peculiar advantage of this relay-instrument (as it is called) that the temporary magnet has no other work to do than to turn the permanent magnet upon its almost frictionless pivot. It has no spring to overcome, such as is more commonly employed in the class of instruments. The arrangement is so sensitive that the apparatus may be put in action by a fragment of zinc and a sixpence pressed against the tongue. These relays may indeed be ordinarily heard clicking along the telegraphic instruments, and it is common in large telephone offices when the large induction-coils are in operation within a few feet of them, actually doing a little business on their own account, although not in communication with any current, and transmitting the same signals and messages as those which are being forwarded through the agency of the induction-coils.

As the poles of the induction-coil magnets are reversed, the poles of the relay-magnets are actuated differently. Mr. Whitehouse has made the instruments even more exquisitely delicate by applying a second permanent magnet, so that it complements in the sense of like poles to increase and diminish the attraction acting on the working magnet, either way.

When the printing battery is brought into operation by the instrument just described, it records by the agency of one of Professor Morse's telegraphic instruments. A ribbon of paper is unrolled from a hollow cylinder by a train of clock-work, and as it is unrolled, a sharp style, magnetically actuated, indents a series of dots or lines upon the paper. When the style is pricked down, but for an instant, it is a dot that is impressed. When it is kept down for more than an instant a lengthened line or dash is left, because the paper ribbon is being drawn along beneath the style. In order that the style may be magnetically controlled to inscribe the Morse characters, it is held up by a spring which is not in action, and drawn down by a temporary magnet formed by the printing battery current, when in operation. A soft iron bar, enveloped by a coil of the printing battery wire, is stronger than the spring when it becomes a magnet, and draws it down.

The dot and dash-code of Professor Morse is adopted for the Atlantic service, because there is but one wire in the cable, which must be made to express, at least, all the letters of the alphabet, and all the numerals; different combinations of the dot and dash can be readily caused to express this; thus dot and dash, — is taken to signify a; . . . to signify b; , —, for c; ;; for d; c e so on. Mr. C. Bight has patented a very ingenious piece of apparatus in which the Morse characters are given symbolically, by symbols issuing from a free and a muffled bell. It is possible that this apparatus will some day be adopted by the Atlantic Company for their service.

Her Britannic Majesty's Government granted to the Company the use of the fine 31-gun ship Agamemnon for paying out one half of the cable into the Atlantic, and commissioned the paddle-wheel frigate Leopard to act as its tender. The United States Government sent over the magnificent new heavy frigate Constitution to carry the other half, with the paddle-wheel steamer Susquehanna for a tender. The Agamemnon proved to be singularly adapted for its work in consequence of having one square space as a hold, 49 feet across and 20 feet deep. In this space the 1200 miles of cable was paid out in one day, the cable being singularly coiled. The Niagara was not by any means so well adapted for the service, and had to be considerably altered in her internal arrangements after she came over to England, the cable being loaded, and then being distributed into three or four distinct coils. This was done by having the cable payed out, planned that the cable should come up from the hold of the ship, sweeping round a central block occupying the width of the coil, and then wound out and in over four grooves cut to a central core together by cogs, finally passing along a short distance above the poop-deck, and plunging over a fifth sheave, resting over the stern, into the sea. A friction drum, also geared to the sheaves, was embraced by block and tackle, and powerful screws, so that it could be gripped more or less tightly whenever occasion arose. Provision was also made to register electrically the speed with which the pay-out vessels moved through the water, the rate at which the cable was payed out, every instant, and the strain which was thrown upon it. Electrical signals, too, were to be made through the cable, from end to end, every second, to prove the maintenance of its continuity. The engineer's calculations fixed from four to five miles an hour as the rate at which the cable should be paid off. An external guard was placed over the screws of the vessels engaged in the work, to prevent the cable being injured in case any need should arise for returning upon the course to pick up signals sent from the opposite end of the cable. When the storm was past, the dropping being accomplished by means of very strong supplementary ropes kept ready for the purpose.

The end of the month of July was selected for the accomplishment of this wonderful enterprise, because Lieutenant Manly had ascertained, by the accumulation of a large series of observations, that the Northern Atlantic is in the most favorable condition for any work of the kind in this season of the year. There is then the least likelihood of trouble from ice, and the strength of the wind is never so great that it can be considered as a hazard. The wind is almost unknown at the period, excepting just off the western coast of Ireland. Lieutenant Manly also marked out the track the vessels ought to endeavors to take. Theoretically, the course lay off the coast of Newfoundland, and in the first instance, it was determined to use the great circle route. But all practical navigators are aware that it is altogether impossible to direct a ship along a true great circle track. Such a track would require the course of the vessel to be altered at an infinitely small amount at every successive instant. Whereas in steering by the compass no alteration of, course, to any thing less than half a point of the compass is actually trustworthy. Bad steering, unaccertainable sets of the current, and the change in the weather, made the ship have errors nearly approaching to this amount. Lieutenant Manly consequently planned a polygonal route from Valentia Harbour to Trinity Bay, in which there were only six changes of course, each one restricted to a quarter of a point of the compass, and in which the departure from a true great circle path was no more than eight-tenths of a nautical mile.

If one ship had sailed in the great circle route, and the other in the polygonal route, each moving at the same rate of speed, the error of the course of the vessel would be altered to an infinitely small amount over the whole way. The telegraph cable being laid in the polygonal route, and then hauled in by windlasses at each end, until it was reduced to a true great circle curve, each windlass would only have to wind in 300 fathoms of the cable. The entire length of the cable from Valentia Harbour to Trinity Bay would be 1834 statute miles. The liberal allowance of a superfluous length of 600 miles was therefore made to provide against unforeseen accidents.

In recent years very great improvements have been made in the process of deep sea sounding, chiefly in the first instance through American ingenuity and skill. Mr. Brooke, of the United States navy, has contrived a sounding apparatus, which proves very successful and manageable. The apparatus consists of a cannon-ball thrown upon an iron rod in such a way that when the rod strikes the bottom of the sea the cannon ball is detached from a pair of triggers and dropped, the rod being then drawn up with specimens of the bottom of the sea, which are preserved in very single form. Allowance is made for the extent to which transverse currents draw out the line during the descent of the plummet, based upon the known rate at which the plummet ought to descend in deep water. It appears from a large series of observations, deep water in the North Atlantic, that the depth of the bed of the Atlantic is very much, and very abruptly broken up; jagged peaks alternating with precipitous submarine valleys. The greatest depth of the Atlantic seems to lie to the south of the banks of Newfoundland, the sounding there indicating a descent of at least 3,000 fathoms. In the more northerly regions the depth is considerably less, especially between the parallels of 48° and 55° north latitude. There is one great zone of the earth, extending from east to west, in which the surface appears to be raised comparatively high. This zone marks the line in which the northern and southern water-heds meet, alike in the continents of America, Europe,
It is continued in the Northern Pacific through the Aleutian Islands, and it stretches at the bottom of the Atlantic, as a sort of organism from which brought up by the land to Cape Clear in Ireland, Newfoundland and the British Islands being really projecting extremities of the higher portion of the shelf. This platice rests precisely in the course along which the beds of the deep sea plummet prove to be so perfect notwithstanding their fragility, that there can be no doubt the depths where they lie are free from all kinds of mechanical disturbance, and so in the precise condition which must be the most conducive to the safe preservation of an electrical cable once deposited in their recesses. Lieutenant Berryman, of the United States navy, carefully sounded through the extent of this submarine plateau, and described it as being smooth and slightly inclined from north to south. The sounding boat had been revised those soundings shortly before the sailing of the expedition for the submergence of the cable, going over the same track again, and fully confirmed the general facts of the relatively slight depth of the plateau, and the abundant presence of diatomaceous ooze. The searching boats were directed to report a greater degree of density in the depths of different positions than Lieutenant Berryman had conceived.

On the 5th of August, 1857, operations commenced. There were present the *Agamemnon*, *Niagara*, *Leopard*, "Suspect", "Vulcan", "Mind," which were intended to assist in various parts of the operations. The shore-end of the cable was taken on shore from the "Niagara," by a number of boats. And then took place a ceremonious inauguration of the enterprise; the Lord Lieutenant of Ireland receiving the extremity of the cable, and drawing it into a tent where electrical batteries had been placed, on the beach of Valentia Harbour. The engineer was doomed, however, to a mortifying disappointment. A slight accident happened to the cable on the 6th, but this was repaired, and the ships proceeded. By the morning of the 10th they had got out 200 miles to sea, and the cable conveyed messages to and from the land and the ships with the utmost facility; the persons on shore following the history of the voyage hour by hour, and receiving the messages at the extremity of it. At the latest statement, 360 nautical miles, or 800 statute miles, of cable had been submerged; and, knowing that was far too much in proportion to the straight line distance, he concluded there was too much cable in the bag. The cable was thereupon rejected, and the ship of the engineer was therefore made; and this modification appears to have been usefully adopted by one of the subordinates. The cable was stretched too tightly; it was matted, and went to the bottom, at a depth of twelve thousand feet, equal to forty times the height of St. Paul's. Preparations are being made at this time, March 1858, for immediately resuming the attempt. The last portion of the cable has been replaced; and government ships of Great Britain and of the United States are under orders again to assist in this national enterprise.

Electrical Telegraphs now render useful service in several cities of America. In New York eight bell-towers are connected with each other, and with the central tower over the City Hall, and the new tower in the Narrows, and these form an alarm of fire. At Boston a comprehensive plan is acted on. A central station has been selected, in which the principal instruments are placed. Two wires take a very circuitous route from this station; one, ingeniously supported on a mast, is held to the central station by means of bell-towers in the city, where it sets upon machinery which strikes on a large bell whenever an impulse is transmitted through the wire; the other, much more extensive, proceeds to all the street or ward signal-stations in the city. At each of these signal-stations is a box containing a magnetic galvanometer, under the care of a keeper. If a fire break out in any part of the city, a message is sent to the nearest signal-station; the man transmits a signal to the central station, whence an electric impulse is sent to all the bell-towers in the city, the ringing of which conveys the required information. It is obvious that other public service, besides that relating to fire, may be assigned the electrical means. There are about fifty miles of wire in this telegraph at Boston. There seems every reason to believe that, now the telegraphic wires follow so many sub-way routes in the town, the glass tube will gradually be brought within the scope of the system.

**ELECTRICITY OF ORGANIC BEINGS.** Plants and animals, under certain circumstances, exhibit electrical phenomena. These however are not so constant or frequent as those observed on the bottom of the sea; but that is now known to exist between the great forces of nature, as Light, Heat, Chemical Action, and Electricity, it is perhaps matter of surprise that so few electrical phenomena are exhibited by organised bodies.

In Plants it appears that during growth electricity is developed. Pouillet filled several pots with earth, and placed in them different kinds of seeds, and then insulated them. During the process of germination no electric disturbance was discovered, but when the seeds began to sprout a gold-leaf electrometer had become separated at least half an inch from each other. Pouillet concludes that the vegetation on the surface of the earth must produce a vast amount of electricity, and be an active cause of its phenomena in nature. It has been observed that the use of wires in the bark and pith of a growing tree, they have obtained decided indications of the presence of a galvanic current. These exhibitions of electric disturbance are undoubtedly dependent on the chemical changes going on in the plant, and this is shown by the fact that in the use of a gold-leaf electrometer in nature representing another. Under the influence of heat and light the chemical and attractive forces are brought into play, and the motile force of the growth of the plant as well as electrical phenomena are the result.

In the Animal kingdom the phenomena of the presence of electricity is afforded during the activity of the vital functions. Matteucci has observed a considerable deflection of the galvanometer when wires were connected with the muscles and nerves of the human body. The electricity is excited by the movements of the human body. This is made evident by rubbing the feet on a woolen rug, when, on the application the hand to a gold-leaf electrometer, the presence of electric disturbance is indicated. Some persons are more liable to this development than others, and Dr. Carrel's experiments on dogs and other animals prove the existence of this current. These and other experiments of the Matteucci and Du Bois-Raymond have shown not only that free electricity is developed in animal bodies, but that there is a true galvanic current both in the muscles and nerves. Galvani attributed the movements, first observed by his wife, induced in a frog's leg by wires placed on the ear and body. Volta showed that the movements observed by Galvani were dependent on the chemical action developed in the muscles. Matteucci observed the peculiar sensitiveness of the nerves and muscles of the frog to galvanic action, and made use of the leg, prepared as a galvanometer, in many of his experiments. The mode of using it was simply to take the leg of a recently-killed frog with the crural nerve dissected out of the body, but remaining in connection with it. The leg was then inclined in a glass tube, covered with an insulated wire, and the terminal of this open end. When two points of the nerve thus prepared are brought in contact with any two substances in a different electrical state, the muscles of the frog's leg are thrown into contraction. By this galvanic test, the frog's leg was enabled to detect currents of electricity in the muscles of animals, by cutting into them, and placing one extremity of the nerve deep in the wound and the other at its tips. The experiments of Matteucci were followed up by Du Bois-Raymond, who has recently concluded that negative or positive currents may be observed in any limb of any animal whether cold or warm-blooded. These currents in some limbs are directed downwards, in others upwards. They are of different intensity in different limbs; but their intensity and direction are always the same in the same limb of different
individuals of the same species. 2. The electro-motive action on which these currents depend does not arise from the union of the two transverse sections, or the 3. The currents are produced by the muscles. If any undissected muscle of any animal be brought into the circuit longitudinally, the discharge is instantaneously cut off, and the direction of which depends on the position of the muscle. The current of the whole limb is nothing but the resultant of the partial currents which are engendered by each muscle of the limb. It is therefore a 'muscular current.' 4. The law of discharge is this: 'Any point of the natural or artificial longitudinal section of the muscle is positive in relation to any point of the natural or artificial transverse section.' 5. By means of the above-mentioned phenomena it is asserted that the transverse section appearing in one instance an upward one, in another a downward one, which occurs according as the upper or the under of the two transverse sections is made to touch one of the ends of the galvanometer wire, whilst the other end is applied to the longitudinal section of the muscle. This is true even as regards shreds of muscle consisting of only a few primary fibres, and such as only admit of observation by the microscope. The nerves are possessed of an electro-motive action, but it is peculiar and not to be compared with that possessed by the muscles. Whilst still in organic connection with the muscles, and forming part of a circuit in which the muscles give rise to a current, the nerves simply play the part of an inactive conducting body, provided their own current be prevented from reaching the galvanometer.

There are certain animals which possess the power of accumulating electric force within their bodies, and of discharging it at will in a violent form, and with the exception of some insects and Mollusca which have been said (though this is done) to communicate sensible shocks, these animals are all included in the class of Fishes. About seven species of this class, belonging to five genera, are known to possess electric properties, and it is curious that these genera belong to the same family. From this it appears, that though each has a limited geographical range, one species or other is found in almost every part of the world. Thus, the three species of Torpedo, belonging to the Ray tribe, are found on most of the coasts of the Atlantic and Mediterranean, and sometimes so abundantly as to be a staple article of food. The Gymnotus, or Electric Eel, is confined to the rivers of South America. The Sihurus (more correctly the Malapterurus), which approaches more nearly to the Salmon tribe, occurs in the Niger, Benue, and the Nile. The Torpedo Club, or Electric Ray, is found in the Indian Seas; and the Tetradon (one of the genus allied to the Diodon, or Globe-Fish) has only been met with on the coral banks of Java, one of the Comoro Islands. These fishes have been variously called the Salmon, the Ray, the Electric Ray, and the Electric Eel, but it seems probable that the phenomena which they exhibit, and the structural peculiarities with which these are connected, are essentially the same throughout.

The peculiar characteristic of all is the power of giving to any living body which touches them a shock resembling in its effects that produced by the discharge of a Leyden jar. This is of very variable intensity in different species and individuals, and at different times. The Gymnotus will attack, and paralyse horses, as well as kill small animals, and the discharges of large fish (which are 30 feet long) sometimes prove sufficient to deprive men of sense and motion. The effects of the contact of the Torpedo are less severe, and soon pass off; but the shock is attended with considerable pain whenever the fish is vigorous. The electric organs appear to be charged and discharged to a certain extent at the will of the animals. Their power is generally exerted by the approach of some other animal, or by some external irritation; but it is not always possible to call it forth, even when conditions are apparently fulfilled. A fish with the general feebleness of the system, though sometimes a dying fish exerts considerable power. All electrical fishes have their energy exhausted by a continued series of discharges; and when they do not pass, however weakly South America to collect a number of wild horses and drive them into the rivers, in order to save themselves, when they pass, from being injured by the fish. If excessively exhausted, the animals may even die; but they usually recover their electrical energy after a few hours rest.

The Torpedo, from its proximity to European shores, has been most frequently made the subject of observation and experiment; and the following are the most important results from those experiments:—

1. That the shock received by the organs of sensation in man is really the result of an electric discharge, has now been fully established. Although no one has ever seen a spark emitted from the body of one of the fish, it may be easily shown that it is electric, and that these animals send its discharge through a slightly interrupted circuit. The galvanometer is influenced by the discharge of the Torpedo, and chemical decomposition may be effected by it, as well as magnetic properties. In communication with the professor, a proper reception of the shock, that two parts of the body should be touched at the same time, and that these two should be in different electrical states. The most energetic discharge is procured from the Torpedo by touching the belly, and passing the hand around the side, so as to make the dorsal surface being positive, and that of the ventral negative; and by this means the galvanometer may be strongly affected, every part of the back being positive with respect to every part of the opposite surface. When the two wires of the galvanometer are applied to the corresponding parts of the two sides of the same surface, no influence is manifested; but, if the two points do not correspond in situation, whether they be on the back or both on the belly, the index of the galvanometer is moved, and it is found that the discharge to the electric organ appears to be the source of the difference in the relative state of different parts of the body; those which are near to it being always positive in respect to those more distant. Dr. Davy found that, however much Torpedoes are used to the discharge, they never become insensible to single non-sensory shocks at all, and he states that, when one surface only is touched and irritated, the fish themselves appear to make an effort to bring the border of the other surface, by muscular contraction, into contact with the offending body; and that this is even done by fish in London to the Plates of metal, the edges of which are in contact, no shock is perceived by the hands placed upon them, since the metal is a better conductor than the human body; but if the plates be prevented from coming in contact with each other, the sides of the body, the hands being applied to them, the discharge is at once rendered perceptible, and it may be passed through a line formed by the moistened hands of two or more persons, the extremities being brought into relation with the opposite plates. The electrical phenomena of the Gymnotus are essentially the same with those of the Torpedo; but the opposite electrical states are found to exist, not between the dorsal and ventral surfaces, but between the head and tail; and it is most powerful when the connection is formed between these extremities.

It has been ascertained by experiment, that the manifestation of this peculiar power depends upon the integrity of the connection between the nervous centres and certain organs which are considered as the electric organs of the fish. These organs are of a flattened shape, and occupy the front and sides of the body, forming two large masses, which extend backwards and outwards from each side of the head. They are composed of two layers of membrane, between which is a whilish soft pulp, divided into columns by processes of the membrane sent off so as to form partitions like the cells of a honeycomb; the ends of these columns being directed towards the two surfaces of the body. The columns are again subdivided horizontally by more delicate partitions, which form each into a number of distinct cells; the partitions are extremely vascular, and are profusely supplied with nerves, the fibres of which seem to break up into minuter fibrille to form plexuses upon these membranes. The fluid contained in the electric organs forms so large a portion of the body, that the specific gravity of the mass is only 1.026, whilst that of the body in general is about 1.060; and from a chemical examination of its constituents, it seems to be little else than water, holding one-twelfth part of albumen in solution, with a small quantity of the Tetrabromide of Barium. The electric organs are essentially the same in structure, though differing in shape, in accordance with the conformation of the animal; they occupy one-third of its bulk, and run along nearly its whole length; but are formed of two different parts, one much larger than the other. The primary mass is less unusual, but are much longer; for they run in the direction of the length of the body, a difference which is productive of a considerable modification of the character of the discharge. In the Sihurus there is not any electrical organ so definite as those just described; but the thick layer of dense cellular...
time, which completely surrounds the body, appears to be subservient to this function; it is composed of tendinous fibres interwoven together, and of an albuminous substance contained in their interstices, so as to bear a close analogy with the cellular partitions in the special organs of the *Torpedo* and *Gymnotus.* The organs of the other known electrical fishes have not yet come under the notice of any anatomist.

In all these instances the electrical organs are supplied with a mass of very great size, larger than any others in the same animals, and larger than any nerve in other animals of like bulk. They all arise in the *Torpedo* from a ganglionic mass situated behind the cerebellum, and connected with the medulla oblongata. It has been observed that these two organs arise in the second of them from the cruciate in close proximity with the fifth, and have been regarded as belonging to it, although their real origin is different; whilst, from the distribution of the third electrical nerve to the stomach, after sending its principal portion to the electrical organ, it would seem analogous to the eighth pair or pneumogastric.

The electrical nerves in the *Gymnotus* are believed to arise from the spinal marrow alone; and those of the *Silurus* are supposed to arise from the same nerve, and to be connected with the medulla oblongata. The integrity of the nerves is essential to the full action of the electrical organs. If all the trunks be cut on one side, the power of that organ will be destroyed, but that of the other may remain uninjured. If the nerves be partially destroyed, a part of the electric power may be recovered by the portion of the organs still in connection with the centres. The same effects are produced by tying the nerves as by cutting them. Even slices of the organ entirely separate from the body, kept by nerve fibres, may retain the electrical properties. Discharges may be excited by irrita-
tion of the brain when the nerves are entire, or of the part of the divided trunk distributed on the organ; but on de-
stroying the electric lobe of the brain the electric power of the animal ceases entirely; a place is usually taken by those centres which are removed by imperilling the electric organs. Poisons which act violently on the nervous system have a striking effect upon the electric manifestations of these fish; thus, two grains of muriate of morphia were found by Matteucci to produce death after about ten minutes, during which time the discharges were very numerous and powerful; and strychnia also excited powerful discharges at first, succeeded by weaker ones, the animals dying in violent convulsions. When the animals were under the influence of strychnia it was observed that the electrodes of the organs did not answer to the table on which the animal was placed being sufficient to produce this effect. If the spinal cord were divided, how-
ever, no irritation of the parts situated below the section called into action the centres above; and it is certain that the electric power is suspended when the *Torpedo* is plunged into water at 33°, and is recovered again when it is immersed in water of a temperature from 68° to 66°; and that this alternation may be repeated several times upon the same fish. But if the temperature be raised to 68° the *Torpedo* soon ceases to live, and dies while giving a great number of violent discharges. (Carpenter.)

From these facts it is evident that the electric force is developed as the result of nervous agency. From this it has been supposed that the electric and muscular forces are identical. This, however, is not more probable than that the contractile force of the muscles is identical with the nervous force. The best explanation of the pheno

Carpenter, Principles of Physiology, General and Compara-

**ELEOTRIS**, a genus of Acanthoperciform Fishes belonging to the family Gobidae. Like the Gobies the species have flexible rays in the fins, and a strong electric organ situated behind the vent, but they have the ventral fins separate and six gill-rays. The species are inhabitants of the fresh waters of warm countries, and conceal themselves in the mud of the natal river.

**E. domatricha**, the Sleeper, is a large fish. It is found in the West Indian marshes. Other species have been found in Africa, India, and the Mediterranean.

**EILDONE. [EILIDONE.]**

ELLENBOURGH. [CUMBERLAND.]

ELLENBOURGH, LORD. Edward Law was born November 16, 1760, at Great Salkeld, in the county of Cumber-
land. He was the fourth son of Dr. Edmund Law, bishop of Carlisle. He received his rudimentary education at the conventual schools of his native place, and was sent to Dr. Burn, an eminent Lea-
tician, who then resided at Docking in Norfolk. He was re-
moved thence in 1782 to the Charter-house School, London, and placed on the foundation. In 1788 he entered of St. Peter's College, Cambridge. After taking his degree of B.A. he removed to St. John's College, and was admitted to the Inner Temple. Having been called to the bar, and ac-
quired by a short preparatory practice the needful technical knowledge, he soon took his place among the chief members of that body. He was engaged as the leading counsel in the defence of Warren Hastings, 1788 to 1795, and in this famous trial acquired great distinction both as a lawyer and a speaker. In Westminster Hall he had Erskine and other able rivals to contend with, and never rose to the first lead of the case, but always remained the most popular in the Northern Circuit. His rise in the profession was remarkably rapid. In 1801 he was appointed attorney-general and knighted, and in the same year he was elected a member of the House of Commons. In April 1808 Sir Edward Law succeeded Lord Kenyon as lord chief justice of the court of King's Bench, and was created a peer by the title of Baron Ellenborough, ofEllenborough in Cumberland, by patent dated April 10th, 1808. He was afterwards made a privy councillor. In the House of Lords in 1805 he strenuously opposed any concession to the Roman Catholics. On the trial of Lord Melville in 1806 Lord Ellenborough voted against him. In 1813 he was nominated one of the com-
mis sioners to inquire into the conduct of the Prince of Wales. In 1816 he was the leading counsel in the trial of Lord Cochrane, and in 1818 on the trial of Hone. [Hone, William, S. i.] In November of the same year he retired from the bench. He died December 13, 1818, at his residence in London. He married in 1802, and was succeeded in the title by his eldest son, who is now Earl of Ellenborough. Lord Brougham, in his *Historical Sketches of Statesmen,* makes the following remarks on his character as a judge:—"The Term Reports bear ample testimony to the vigour of this eminent indi-
nual's capacity during the sixteen years that he filled the first place among the English common-law judges. . . . He was somewhat irascible, and sometimes even violent. But no one could accuse him of the least partiality. His decisions were prompt and just, and he was much to trample overbearingly on the humble as to crouch meanly before the powerful. . . . He despatched business with great celerity, and for the most part with success. But causes were not sifted before him with that care and accuracy which the duties of the office required, nor suffered to bring forward all they had to state with that fulness and freedom, which alone can prevent miscon-
untenance, and ensure the due administration of justice."

ELLESMERE, EARL OF. LORD FRANCIS LIVESTON GOWAN was created Earl of Ellesmere on the death of his father, the second son of the first Duke of Sutherland, and brother of the present Duke. He was educated at Eton College, and afterwards at Christ Church, Oxford. He left the university in 1820, in which year he was called to the Bar at the New Inn. He married in 1826, and was times disenchanted by the Reform Act. At a time when the German language was little studied in England he distinguished himself by a translation of the *Faust* of Goethe, in two volumes, which was more than
translated from the original, which was written in 1843, and published in 1844, as "The Autobiography of Baroness Sutherland of Eoebton."
everywhere a thoroughly honest hatred of oppression, and fellow-feeling with the oppressed and suffering. With quite a Crabbe-like familiarity with the poverty of the poor, they displayed a far warmer, deeper, and more genial sympathy. The wrath and the pathos, too, uttered in the most impassioned and the most direct words, were yet conveyed in genuine music, which made its way at once to the heart.

Wings and attend anterior art, the He Corn-

dramatic epigrams, during to the the Language architectural partnership, this, burning felt the the design on his first music-hall laid the design for his office at Mortlake, in Sir Mr. Cockrell, who also designed the sculpture of the pedestal.

To understand the importance of Elmes's great work, it would be necessary to review the history of architecture, and especially the adaptation of Greek models, during the course of some years preceding the date of the St. George's Hall design. The proper use of ancient models had been completely lost, and even at the time to seek architec-true. In many parts of the kingdom buildings were erected, supposed to be classical, but which realised neither art nor the lower quality, the very imitation. Thus an idea had begun to prevail that the Greek system was so limited in its scope, that no satisfactory type of modern buildings could be in itself the cause of the failure in certain ambitious pro-
ductions. Elmes however repeated the proof that it was possible to use the works of preceding minds, and yet to realise the grandest new conception. Considered as to the attributes of art, Elmes's work is more Greek than many modern buildings which may exhibit even accurate reproduction. The design may well be claimed by this country as amongst the noblest efforts of architecture in Europe.

After years spent most worthily in the pursuit of art, Elmes had not realised anything commensurate with the ex-
tent and merit of his exertions. An average of 4000 a-year, subject to deductions for travelling, clerks, office and other expenses, would have been expected in that one. He had received from that work which forms the chief adornment of a rich provincial town; and after his death a subscrip-
tion was raised to provide a moderate income for his wife and child.

ELODIANS. [Toxotess.]

EMBERIZIDE, a family of birds belonging to the order Insectivora and the tribe Corvidae. The most distinguishing genus of the family is Emberiza. It comprises however other genera, the general relations of this family are given under Fauquierides. We shall confine ourselves here to the British genera of this family known under the name of Buntings.

Electrophanes.—Bank short, thick, conical, the edges of both mandibles slightly curved inwards; beak able to be used smaller than the lower, with a small palatal knot. Nostrils basal, oval, partly hidden by small feathers. Wings long and pointed; the first and second quill feathers of nearly equal length, and the longest in the wing. Legs with a taral of moderate length; anterior toes divided; lateral toes equal in length; hind toe strong; claw elongated, and nearly straight.

Lappetidae (Gould), the Lapland Buntings, is the Emberizinae lapponica and E. cucullata, first mentioned.

Though a native of the arctic regions, Mr. Rayrell records five instances of its being taken in Great Britain. It is found in Siberia and near the Urallian chain. Towards winter a few migrate as far as Switzerland. It inhabits the large islands of the Baltic, Greenland, and Iceland in sum-
mer, and thence westward to Hudson's Bay. Sir John Richardson says, that about the middle of May, 1827, they appeared in very large flocks at Carlton Hoose, and a few days later made their appearance at Cumberland House. The ages are usually seven, and of a pale ochre-yellow spotted with brown.

P. nicolai, the Snow-Bunting. It is the Emberiza glacialis, E. monica, E. nicola, and E. ustulata of authors; and the Tawny-Mountain- and Snow-Bunting of English writers. It was at one time supposed they were different species, but this arose from the great variety of plumage to which these birds are subject. The predominant colour of their plumage is white, hence the name Snow-Bunting. This bird arrives in the arctic region in the beginning of October, and extends from the north of Scot-
land to the south of England. This bird is rather larger than the last.

Emberiza—Beak conical, strong, hard, and sharp-pointed; the edges of both mandibles curving inwards; the upper mandible narrower and smaller than the under one, and its roof furnished with a hard bony and projecting palatal knob. Nostrils basal and round, partly hidden by small feathers at the base of the mandibles. The yellow of the back of the plumage is shorter than the third, which is the longest in the wing. Feet with three toes before and one behind, divided to their origin; claws rather long, curved, and strong.

E. melitens, the Common Bunting, is the most common species of this genus. It remains in the British Islands
throughout the year; and on account of its very familiar presence in corn-fields, is frequently called the Corn-Bunting. It builds its nest in April, and lays four or five eggs of creamy white, marked with purplish streaks and spotted with dark purple-browns. It feeds on the seeds of the grasses, of the Polygona, of sorrels, and of cereal plants; also on Coleopteraeous Insects.

In both sexes of this species the upper parts are of a light yellowish-brown streaked with blackish-browns, each feather being of that colour along the shaft; lower parts pale yellowish-gray, each feather of the fore neck tipped with a triangular spot of brownish-black, the fore part of the breast and flanks streaked with more elongated and fainter spots.

E. schenicus, the Reed-Bunting. It is also called, according to MacGillivray, Black-Headed Bunting, Reed-Sparrow, Water-Sparrow, Ring-Bunting, Ring-Bird, Ring-Fowl, and Ginch. It frequents marshy places, where it is seen perching on willows or bushes. It feeds on insects, seeds, and small Mollusca. The nest is placed among aquatic plants, and is composed of stalks and blades of grasses, bits of rushes, and the like. The eggs are four or five in number, of a yellowish-gray, with tortuous or angular lines, and irregular spots of black. This bird is easily distinguished from the other species by its black head and white throat.

E. citrinella, the Yellow Bunting or Yellow Ammer. It is also called in English Yellow Yelling or Yolding. Yellow Yowley, Yellow Yite, Yeldock Skute, and Devil's Bird. It is a permanent resident in Great Britain, in cultivated and wooded districts, where it is well known. The hack and wings are bright red, the central part of each feather brownish-black. The whole of the grassland is twigs, neatly lined with fine grass, fibrous roots, and hairs: it is placed on the ground or in the lower part of a bush. It lays four or five eggs purplish-white, marked with linear and angular streaks and a few irregular dots of black.

E. Circus, the Cirl-Bunting. This bird is not so common in this country as the last, which it greatly resembles. It was first distinguished as a British bird by Colonel Montagu. It is a native also of the south of Europe, and is more frequent in the England than in Ireland.

E. hortulana, the Ortolan Bunting. A very few specimens only of this bird have been taken in England. It is common in the southern countries of Europe, and migrates as far northward as the Baltic. (MacGillivray, Manual of British Birds; Yarrell, History of British Birds.)

EMISSION. One of the most remarkable facts in the history of Great Britain is the rapid increase of the population in the 19th century, which is pointed out in the article Census. While the population of France and Germany has increased within the last fifty years in a very small degree; while in Spain, Portugal, and Italy it has probably decreased; Great Britain has increased from 10,800,000 in 1801, to 30,900,000 in 1851, and to 40,900,000 in 1861; and in the middle of 1866, the Registrar-General estimated the population of England and Wales alone at 39,044,000: Ireland is omitted, as there was no census of 1801. In addition to this increase, swarms have been thrown off to which the ancient migrations from the North are insignificant in their total amount, though the emigration has been less striking from its being not an irruption but a gradual process. In forty-two years, from 1815 to 1856 inclusive, during which among an average emigrant has been taken, 4,470,219 persons, male and female, have left the shores of the United Kingdom; and these have been enabled to form what may now be termed three mighty empires, subordinate to our own, in Australia, New Zealand, and South Africa; independent of the branch streams which have flown off to Ceylon, the West and East Indies, Guiana, and other British possessions. The United States of America is the only domain that can afford any considerable emigration, and that is indebted to it for 2,703,782 persons, who have proceeded thither, the greater proportion of whom have been from Ireland, and chiefly from the years beginning with 1847. The annual average of emigration from Ireland, 1846, was 161,255; from 1847 to 1856, it was 279,816. It should be added here, however, that from 1815 to 1824 no records were kept of the emigration to South Australia and New Zealand; but it was certainly under £10,000 a year. In the ' Penny Cyclopaedia' (vol. ix. p. 377; article Emigration), we gave a table of emigration to 1856, which we now complete to 1857:

In 1857 the total number of emigrants from the port of Liverpool only, was 155,052; of these 9788 were for the North American colonies; 106,918 for the United States; 22,851 for Australia and New Zealand. We have now data for other places. Of these emigrants England supplied 60,689; Scotland, 6191; Ireland, 71,195; and various foreign countries, chiefly Germany, 6414. The emigration to Australia was principally English; that to the United States principally Irish.

Many emigrants, however, proceeded to the North American colonies by New York, and no account is taken of the passage either way on the borders between them and the United States. The proportions thus computed are probably more fertile than at home. We give the latest returns of the population of these colonies which are mainly occupied by a British population, our youngest and most vigorous:

The numbers given for Canada are from the Census of 1851 for Western, and the official return of 1852 for Eastern Canada; the estimated numbers of both in January 1857 were 2,600,000. For New Brunswick they are taken from the Census of 1851, and the official returns of 1853. For Nova Scotia, from the Census of 1851. For Prince Edward's Island, from the Census of 1851, and the official return of 1857 at 12,000. All have increased since the returns. For Newfoundland the numbers are taken from the Census of 1840, and in 1857 the increase was estimated at 10,000. For Bermuda the authority is the official return of 1853.

These returns all come down to a recent date, 1855-56, except New Zealand, for which the numbers are from the Census of 1851, and is exclusive of military and aborigines.

In Tasmania are included 7740 convicts, 895 troops, and 19 aborigines. The population of Victoria on Dec. 31, 1855, only three months later than the above return, was estimated at 313,379; and on Dec. 31, 1857, at 4,057,000.

The returns of these colonies are for 1853 and 1854; and in Natal the numbers given are exclusive of 12,988 settled natives.

In these three divisions of the British colonies, there are non-representative governments, the privilege of self taxation, and the right of a free press; in short, a complete reproduction of the British Constitution. To other colonies, especially to British Guiana and some of the West India Islands, the emigration has been considerable; but as the emigrants become mixed with an older and in some cases ....
In and but general a royal best much for business enabling ship, rules their mouth, information Commissioners. that grants me terms, the latest in the 18 and 10 Vict. cap. 119, passed in 1856. Its objects are to regulate the number of passengers in each ship, and to provide for their proper accommodation on board; to ensure a proper supply of provisions and water for their maintenance, and against personal injury, to secure a sufficient number of boats in case of accidents; and to protect emigrants from the numerous frauds to which at various stages of their undertaking their helplessness and inexperience expose them. If the ship does not sail on the day appointed in the agreement the Passenger's Act compels the captain to victual the emigrants just the same as if the voyage had commenced; and they are entitled to remain on board forty-eight hours after the ship reaches her destination.

As a further protection to emigrants, and to enforce the provisions of the Passenger's Act, government emigration agents are appointed for the ports of London, Liverpool, Plymouth, Southampton, Glasgow and Greenock, Dublin, Cork, Belfast, Hull, New York, Greenock, Sligo, Londonderry, and Galway. These officers act under the immediate directions of the Colonial Land and Emigration Commissioners. They procure and give gratuitously information as to the sailing of ships, and means of accommodation for emigrants; and when applied to in this way they see that all agreements between ship-owners, agents, or masters, and intending emigrants, are duly performed. They also see that the provisions of the Passenger's Act are strictly complied with, viz., that passenger-vessels are sea-worthy, that they have provided a sufficient supply of provisions, water, medicines, &c., and that they sail with proper punctuality. They attend personally at their offices on every weekday, and afford gratuitously all the assistance in their power to emigrants arriving from the tropics, and who are not at home, and to obtain redress where oppression or injury has been practised on them.

In the colonies there are Government Emigration Agents at the following places: Canada—Quebec, Montreal, Toronto, and Hamilton. New Brunswick.—St. John's, St. Andrew's, Chatham (Miramichi), Bathurst, Dalhousie, and Richmond. Australian Colonies—Sydney, Moreton Bay, Melbourne, Geelong, Portland Bay, Hobart Town, Lannecost, Perth, Fremantle, Adelaide, and Arrickland. Cape of Good Hope—Cape Town, Port Elizabeth, and Simon's Town.

The duty of these officers is to afford gratuitously to emigrants all the facilities in their power by way of advice and information as to the districts where employment can be obtained most readily, and upon the most advantageous terms, and also as to the best modes of reaching such districts.

The Emigration Commissioners, while they have funds for the purpose, grant passages to New South Wales, Victoria, and South Australia, to persons strictly of the labouring class who may be considered eligible emigrants. The funds are restricted to the amount annually voted, and the administration of them the Commissioners act as trustees for the colonies, and are therefore bound to look exclusively to colonial interests. They do not consider therefore how distress in this country may be best relieved, but how the largest possible number of industrious persons may be procured and sent out. In deciding what classes are most suited to the wants of the colonies, the Commissioners are guided by reports and instructions received from time to time from the governments of the respective colonies, either direct or through the Secretary of the Treasury. The Commissioners are occasionally also able to grant passages to Western Australia; but they have no funds for assisting emigrants to go to the North American colonies. In British Guiana, the Governor and Executive Council, in 1857, of 1854, sect. 4, is authorised by proclamation to name the places from which emigration on bounties is permitted, and to fix the rates of bounty for the introduction of emigrants, under the assistance of the colony, competent and willing to engage in agricultural labour.

Emigration is one of the 'modes of relief' contemplated by the Poor Law Amendment Acts (4 & 5 Wm. IV. c. 76; 11 & 12 Vict. c. 110; 12 & 13 Vict. c. 103; and 13 & 14 Vict. c. 110). Emigrants were at first emigrated with the assistance of funds obtained under the Act 4 & 5 Wm. IV. By sect. 62 of that Act owners and rate-payers are empowered to raise money on security of the rates for the purposes of emigration, under the authority of the Poor Law Commissioners. The sum so raised must not exceed half the average yearly rate of the preceding three years, and it must be repaid within five years. The money is advanced to emigrants by way of loan, and is recoverable by the Union to whom the emigrant has been convicted of emigration, refuses to do so after the expiration of the term fixed, and the loan is also recoverable if persons who emigrate shall return to this country. By the 12 & 13 Vict. cap. 108, the guardians of any parish of the Union are authorised to induce any emigrant to emigrate, or the person emigrating, to furnish to the Poor Law Board, who are to issue their order to confirm the resolution. The 13 & 14 Vict. c. 101, s. 4, enables Boards of Guardians, under similar restrictions, to expend money in and about the emigration of orphans or desert children under sixteen having no settlement, or whose settlement is unknown. But it requires that no emigration of any such orphan or deserted child shall take place without the consent of such child given in petty session, and unless a certificate thereof under the hands of two justices shall have been transmitted to the Poor Law Board. Certain conditions have been laid down by the Poor Law Board in all orders sanctioning the emigration of poor persons, of which the most material is, that the party emigrating shall go to some British colony not lying within the tropics, and having no settlement in it. The Poor Law Board are empowered to pay certain specified sums in the conveyance of the emigrant to the port of embarkation, and on the outfit, including bed, bedding, and clothing.

Under the Irish Poor Law Act, money may be raised for enabling poor persons to emigrate to British colonies; but the money so raised must not exceed one shilling in the pound on the net annual value of rateable property. The Bounty System derives its name from the mode in which the proceeds of sales are applied in obtaining immigrants. In this case persons who introduce persons into the colony receive so much per head, according to the terms of agreement. The contractors engage to find persons willing to emigrate, and undertake to land them in the colony in accordance with one of the terms of agreement. The contractors are in each case responsible for the conduct of the immigrants; and if they neglect to perform their agreement, the money received from the Poor Law Board is applied in indemnifying the contractor for any expense or suffering to which the emigrants may be exposed. In each of the Irish colonies money is paid to the contractors for each ship they bring into the port, and for each passenger they transport to the land. The law makes it obligatory upon the contractors to take particular care of the immigrants, and it prohibits land being alienated by her Majesty, or by any one acting under her authority, except by sale, and in the manner directed by the Act.
Down to the year 1831 no regular or uniform system of selling land appears to have been adopted in the British colonies. The old system of分让 conjure, consisting of the all the claims of the settler, could not be 交寄 to the occupation of land under the name of quit-rents, money payments, or the cultivation of the soil; but these was conditions were not effectively enforced, and in fact was generally found impossible to enforce them. Land was profusely granted to individuals in large tracts, and as cultivation was not enforced, and no roads were made through these tracts, they intercepted the course of improvement. Under the old system, lands in the colony of the Cape of Good Hope are described to as appearing to be subject to be made for a period of 20 years, but in practice these grants have been disposed of for less than 46,000L. In Prince Edward's Island the whole of the land was granted in one day to absentee proprietors upon terms which have never been fulfilled. The influence of these proprietors with the British Government rendered such measures being adopted, as were calculated to enforce the settlement of the grants, and consequently the greater part of them remained chiefly in a wild state. (Report of Mr. C. Beller, M.P., to the Earl of Durham, on Public Lands in British North America, 1838.) This Report contains an account of the system of granting lands in each of the provinces of British North America; and in all of them it appears to have been injurious to the public interests.

In Nova Scotia, commissioners were appointed under the royal sign manual to act as a Land and Emigration Board. The sale of the waste lands of the Crown throughout the British colonies was regulated by the commissioners, and they applied the proceeds of such sales towards the removal thither of emigrants from this country, when the land-fund was appropriated to this object. This board was a subordinate department of the Colonial Office. But the disposal of the waste lands is now, by various Acts of the imperial and provincial parliaments, vested in the local governments. The regulations vary considerably in their details, but we give a summary of the conditions and prices of the waste lands in the North American, Australian, and Cape of Good Hope Colonies.

In Canada there are detached Clergy Reserves for sale in most of the townships surveyed prior to 1841. These reserves are now vested in the Colonial Government by the 48 Vic. c. 21 (1850), subject to the rights of the clergy. They are now thrown open for public sale. The land reported by the chief agent for emigration at Quebec to be the most worthy the attention of emigrants, are the townships Peel, Wellington, Maryborough, and Mornington, covering an area of 250,000 acres, in the county of Huron, Ont. The prices of land in these townships (as of all Clergy Reserves), are regulated by the quality of soil and situation, and average from 8s. to 20s. currency per acre, one-tenth of the purchase money being required at the time of sale, and the remainder to be paid in nine annual instalments with interest. One million acres of land were also appropriated for school purposes by the legislature in 1849, and the school lands in the counties of Bruce, Grey, and Huron are now open for sale to amount to 2,000,000 acres, the terms being 10s. per acre, payable in ten equal annual instalments, with interest. The first instalment to be paid on receiv-

In Canada West, the provincial government have recently opened three great lines of road, and laid out for settlement the lands through which they pass: these are the St. Mary's, the Prince Edward Island, and the Barriefield Road. These roads it will eventually be 171 miles in length, and connect the Ottawa River with Lake Huron. 2nd, The Addison Road, which runs north and south, is 60 miles long, and starts from the settlements in the county of Addington until it intersects the Opeongo Road. 3rd, The Hastings Road, which runs nearly parallel to the Addison Road, is 74 miles long, and connects the county of Hastings with the Opeongo and Opeongo Road. In order to facilitate the settlement of the waste lands in Canada, and to repair these roads in repair, the provincial government have authorised free grants of land along these three roads, not to exceed in each case 100 acres, upon the following conditions—that the settler be eighteen years of age. That he take upon himself the cost of a settlement of one person in a state of cultivation at least twelve acres of land in the course of four years,—build a house (at least 20 by 15 feet) and reside on the lot until the conditions of settlement are fulfilled. Families comprising several settlers belonging to lands, preferring to reside on a single lot, will be exempted from the obligation of building and of residence (except upon the lot on which they live) provided that the required clearing of the land be made on each lot. No title is given to the lot until five years after it has been cleared. The performance of these conditions is thus provided for, and the non-performance of them entails the immediate loss of the assigned lot of land, which will be sold or given to another.

The road having been opened by the Government the settlers are required to keep it in repair. The log house required by the Government to be built is of such a description as can be put up in four days by five men. The neighbours generally help to build the log cabin for newly-arri
ing settlers, and when the building is done, the expense of erection is small; the roof can be covered with bark, and the spaces between the logs plastered with clay, and white-washed; it then becomes a neat dwelling, and warm as a stone house.

The roads in Canada West thus opened up for settlement are capable, both as to soil and climate, of producing abundant crops of winter wheat, of excellent quality and full weight, and of every other description of farm produce grown in the best-cultivated districts of that province.

In Australia and New Zealand licences and leases are granted for large tracts of land for pastoral purposes, at very low rents, as to which the holders have certain restricted rights of pre-emption if required for purposes of cultivation; and subject to the right of being taken by the Government if wanted for public purposes.

In all the colonies the rights of the Crown in regard to minerals are preserved; but in most cases leases are granted on payment of a certain rate per annum. In Canada, the mining laws are 10 per month, for each individual licence, payable in advance; or in case of a lease being granted of a certain portion of land, at a rate of three per cent, on the gross value of the gold procured from Crown lands, and of half that amount on gold obtained from private lands. A 'miner's right' to license and dig for gold is obtainable on payment in advance of 17. per annum. 'Stockkeeper's licenses' at the 'Diggings' are given for three months, 97. for six months, 101. for twelve months.

The Land and Emigration Commissioners are required by their official instructions to prepare and issue "a distinct statement of the most recent statistics of agriculture, the commerce, the manufactures, the physical structure, and the ecclesiastical and political institutions of
EMM, a name used by early English writers for the

Endomosis, a name given by Dutrochet to the process by which fluids pass from the exterior to the interior of a cell. This process seems to result from two distinct agencies, which are always brought into operation where fluids pass through a membrane. The one is the imbibition of the fluid by the porous cell-membrane, and the other is the mutual diffusion of miscible fluids. From the researches of Matteucci and others there can be little doubt that the passage of a gas or liquid through an animal or vegetable membrane is but the modification of the process of attraction by which fluids pass through inorganic bodies. This process is carried on with various degrees of force in different materials, and seems to depend on the degree of attraction subsisting between the particles of the solid and those of the fluid. Matteucci found that when glass tubes of about three-quarters of an inch diameter were filled with fine sand previously dried, and introduced without pressure, and were immersed at their lower ends into the following liquids, the action of imbibition raised the liquids in the tubes to the following heights:

| Solution of Carbonate of Potash | 65 millimeters. |
| Solution of Sulphate of Copper | 70 |
| Serum of Blood | 70 |
| Solution of Carbonate of Ammonia | 62 |
| Distilled Water | 60 |
| Solution of Common Salt | 55 |
| Brine | 65 |
| White of Egg, diluted with its own | 35 |
| volume of water |

In these cases the imbibition took place at first rapidly, then more slowly, and ceased entirely at the end of ten hours. When thick solutions of gum, or starch, or fixed oils were employed, scarcely any imbibition took place, and it was but seldom that even saline solutions approached this degree in which different fluids pass into different solids will be seen in the following table:

<table>
<thead>
<tr>

<td>183</td>
</tr>
</tbody>
</table>

Thus showing that water passed more freely than alcohol into sand, but less freely into saw-dust, and both fluids passed with equal facility into pounded glass. The size of the tubes employed in these experiments and the temperature of the room are not stated. The rise is considerably higher in proportion as the temperature increased. This enables us to understand the influence of heat on life by the physical effects it produces.

Not only is the passage of fluids from the exterior to the interior of a cell facilitated by the attraction between the cell-wall and the fluids, but the fluids on either side of the membrane have a tendency to mix with each other, which cannot but assist in this process. Professors have at times been disposed to think that the latter gives an inherent tendency to mix with each other, independent of the laws of gravity, but that this law also applies to the miscibility of liquids. In a Memoir on this subject in the 'Philosophical Transactions' for 1860, he has shown the laws which regulate the passage of fluids through paper. Different substances possess this property in different degrees. Thus, when solutions of the following substances were used, of the strength of 20 parts to 100 parts of water, the relative quantities diffused in a given time were as follows:

| Chloride of Sodium | 58 |
| Sulphate of Magnesia | 37-43 |
| Nitre of Soda | 51-56 |
| Sulphate of Water | 60-32 |
| Copper | 57-74 |
| Starch-Sugar (Glucoce) | 36-94 |
| Gum Arabic | 13-34 |

The experiments from which these results were obtained, were performed by inverting a phial containing the solution to be diffused in a large jar of pure water. The diffusion was stopped after seven or eight days, and the amount of diffusion determined by evaporating the water of the jar to dryness. There can be little doubt that the substances which diffuse from the juices of plants and animals must have an important influence on the changes which go on in the cells during the performance of the functions of the vegetable or animal body. "Thus," observes Dr. Carpenter, "the low diffusibility of albumen obviously tends to the retention of the serous fluids in the tissues; whilst the high diffusibility of urea will favour its escape from them." The following is an account of the process of Endomosis, and some of the conclusions at which we may arrive from Dr. Carpenter, and直通车 into the following curve a

"If into a tube, closed at one end with a piece of bladder or other membrane, be put a solution of gum or sugar, and the closed end be immersed in water, a passage of fluid will take place from the exterior to the interior of the tube, through the membrane, and the solution of the combined salt will be entirely taken up, and the combined solution will be greatly increased, its strength being proportionally diminished. At the same time, there will be a counter-current in the opposite direction; a portion of the gummy or saccharine solution passing through the membrane to mingle with the water; and the process will be repeated. The first current is termed Endomosis, and the counter-current Exosmose. The increase on either side will be due to the relative velocity of the currents; and the changes will be in proportion to the difference of the tubes used; and so nearly alike as to be incapable of maintaining it. The greater the original difference (provided that the denser be not actually viscid, but be capable of mixing with the other), the more rapidly and powerfully will the process be performed. The best means of experiment is upon the phenomenon afforded by a tube, narrow above, but widely dilated below, so as to afford a large surface to the membrane, compared with that of the superincumbent column, which will then increase in height with great rapidity. By bending this tube in the form of a syphon, and introducing into it a curve and a quantity of mercury, the force as well as the rapidity of the Endomosis between different fluids may be estimated with precision. In this way it was ascertained by Dutrochet, in some of his experiments, that the fluid might be raised against a pressure of no less than 44 atmospheres, or nearly 70 lbs. to the square inch. Although it is not universally true that the activity of the process depends upon the difference in density of the two fluids (for in one or two cases the stronger current passes from the lighter to the heavier), yet it is necessary with regard to particular solutions, as those of gummy or saccharine matter. No endomosis takes place between fluids which will not mingle, such as oil and water; and very little between such as act chemically on each other. Although an organic membrane forms the best septum, yet it has been found that thin laminæ of baked pipe-clay will suffice for the evident production of the phenomenon; and that porous limestones possess the same property in an inferior degree. Although it is not possible to explain the phenomena of Endomosis upon physical principles, yet these will go so far towards it that the general conditions of the process may be considered as well understood. Supposing that two mutually diffusible liquids are on the opposite sides of a porous septum, which is not equally permeable to them; then which is the most readily imbibed will tend to occupy the capillary passages of the septum, and will thus be brought into contact with the liquid on the opposite side. This contact will prevent the fluid from passing into the pores of the septum; and as fast as that which occupies these pores is removed by diffusion, so fast will it be renewed on the other side,—just as oil continues to ascend through the capillary channels in the wick of a lamp, so long as it is being supplied from above. In this way, then, an endomotic current is produced, the force of which will depend upon the diffusion-powers of the two liquids, and upon the difference of the attractive power which the capillary tubes of the septum have for the two respectively.
Thus when a solution of sugar or gum is on one side of the septum, and water on the other, the water is the most readily imbibed, and consequently the chief mixture and diffusion will take place on that side at the surface of the septum in contact with the more viscous liquid. But at the same time this liquid is tending to diffuse itself through the water which occupies the capillary channels of the septum. This is not merely attributable to the difference of density, for the endosmotic current is only attracted by it in a less degree than the water, a portion of it finds its way in a direction opposed to the principal current, and diffuses itself through the water on the other side, thus constituting Exosmose. Thus it happens that the diffusion of the liquids takes place in one of two ways, determined by the attractive power of the septum for one or the other of the liquids; though the diffusion-power of the liquids through each other will help to determine its force. When alcohol and water, for example, are separated by a septum, the alcohol is imbibed from the water towards the alcohol, because the former liquid is more readily 'wets' the membrane, and consequently tends most strongly to occupy its capillary passages; but on the other hand, when the separation is made by a thin lamina of cotton-wool, the endosmotic current is from the alcohol towards the water, because the former is most readily imbied by the septum.

It has further been ascertained by the experiments of Matteucci, that when an organic membrane is employed as the septum, the amount of transport is greatly affected by the direction in which the endosmotic current traverses the membrane. Thus, when the skin of the Torpedo was employed, with a solution of sugar on one side of it and water on the other, although there was always an endosmotic current from the water to the sugar, the current was strong enough to raise the interior liquid to 80° when the water was in contact with the internal surface of the membrane, in the same time that was occupied by its rise to 20° when the external surface of the membrane was turned towards the water. Again, when the mucous membrane of the stomach of a dog was used as the septum, and its external (or muscular) surface was placed in contact with alcohol, the passage of water from the other side took place with such rapidity that the water was raised to 100°, while in the case of a similar but internal (or mucous) surface of the membrane were placed in contact with the alcohol and the mucous surface with water, the current was only sufficient to raise the liquid 6 degrees in the same time; so that it is evident that the transudation of water takes place much more readily from the mucous lining of the stomach towards the outer side of the viscus than in an opposite direction, in virtue simply of the physical properties of the membrane. In fact, according to the experiments of Matteucci, no current is in the cases of fresh membranes, Exosmose takes place with equal readiness, whichever of the two sides is exposed to the water.

The direction which is most favourable to Endosmose through skins is usually from the internal to the external surface, with the exception of the skin of the frog, in which the endosmotic current, in the single case of water and alcohol, takes place most readily from the external to the internal surface. But when stomachs and urinary bladders are employed, the direction varies much more, according to the nature of the liquids employed. This variation appears to have some relation to the physiological conditions in which these membranes are placed in the living animal: thus, the direction most favourable to Endosmose between water and a saccharine solution, is not the same for the stomach of a ruminant as for that of a carnivorous animal; as yet however no positive statement can be made on this subject, however curious and important it may be. The same hold good of the direction of the diffusion-power that have been dried or altered by putrefaction, we either do not observe the usual difference arising from the position of the surfaces, or Endosmose no longer takes place; thus affording another indication that it is to the physical condition of the perfectly undisturbed membrane that we are to look for most of the peculiarities which are noticeable in the transudation of fluids through them. The exosmotic current does not bear any constant relation to the endosmotic, as may be expected from the preceding statement; for if the liquids have different exosmotic and endosmotic powers, and the difference in attractive power which the septum has for them respectively is not great, each may find its way towards the other, and a considerable exosmose may ensue, with very little change of level. The amount of the exosmotic as of the endosmotic current, varies with the direction in which it traverses the membrane; thus, when sugar, alcohol, or gum, was employed in solution, its transudation towards water took place more rapidly than the exosmotic did away from water. If all the skins experi-enced on the principle of imitation of liquids into the tissues and canals of the living body, we shall have to inquire how far they are capable of being accounted for on physical principles which have been now brought forward. It has been maintained by some that absorptive processes in the living body do not occur during the lifetime of the animal, and it has been supposed that all the fluids in the body were stagnant, and another in which an active circulation is taking place. Thus, as Matteucci has shown, if the hind legs of a frog recently killed be immersed for some hours in a solution of furnes potassium, or of a large vein of an animal, be fixed by one extremity to an opening at the bottom of a vessel filled with water, and have a stop-cock attached at the other extremity, and be then immersed in water acidulated with sulphuric or hydrochloric acid, when the tube is allowed to rest in the mixture, the fluid will tend to diffuse itself through the canals or vessels, and to the interior of the tube, which is distended with water; but if the stop-cock be opened, and the water be allowed to discharge itself, the presence of the acid will be immediately discovered (by tincture of litmus) in the liquid which flows out, showing that the acid has been assisted in its penetration of the walls of the tube by the current traversing its interior. Thus, the continuance of circulation is essentially one of the most patent of all the conditions of absorption in the living body; and it is a strong argument, that the dead and living organisms, placed under the same circumstances, may be accounted for in great part, if not entirely, by the stoppage of the circulation in the former. All the circumstances which are laid down by physiology as the conditions are in great measure identical with the physical principles which have been now explained. These circumstances are—1. The readiness with which the liquids are to be absorbed with the juices of the body. 2. The permeability of the tissues through which the absorption takes place. 3. The absence of previous distention in the tissues or canals towards which the flow takes place. 4. The elevation of the temperature within certain limits. 5. The vascularity of the tissues, and the rate of movement of the blood through the vessels. And the results of experiments upon recently-dead membranes which retain almost exactly the same physical conditions as those which they possessed during life, but have entirely lost their vital properties, seem most decidedly to indicate that the action of the exosmotic process is still observable, and the direction most favourable to their passage through the tissues, are determined in great part by the physical relations of those tissues (and of the vessels which traverse them) to the liquid which is seeking entrance thereto. In this then, many of the phenomena of selective absorption are probably to be explained, especially in plants and the lower animals. The special absorbent vessels, however, of Pterisbracteae seem to possess properties which can scarcely be accounted for. ('Principles of Physiology.' [Assomption.])

ENDYMION, a genus of plants belonging to the class of Endogena, the order Dilleniaceae, and the tribe Hemerocollidaceae. It has a tubular bell-shaped perianth, composed of four or five persistent leaves, with reflexed points combined below.
the observations that have been made up to the present time, it appears that these plants are truly in their natural positions in the localities in which they are found, and that they only multiply or become sources of disease when the bodies on which they grow get into a disordered state. In the same manner the patients who seem constantly present in the air and water, only awaiting the proper combination of circumstances to be developed in prodigious numbers. The circumstances which predispose to the growth of these Entophytes upon the body, are not better known than those which predispose the body to receive certain contagions. A failure of the ordinary vital powers to carry on the healthy processes of life seems ordinarily to be the inviting cause of such a development of these plants as would constitute a disease.

All the observations that have been made on this important subject have been brought together by M. Robin in his work on the 'Natural History of the Parasitic Vegetables which grow on Man and on Living Animals' (Paris, 1853). The following is a classification of these plants:—

I. A Dixon.

Class Icocarpea.
Sub-Class 1. Distomaceae.
Sub-Class II. Malacoceae.

Genus P4.0pernias, 11 species.

Genus Molosporas, species.

Genus Tnolphas, species.

Genus Leptotrichia, species.

Genus Chlorophyton, species.

Genus Leptomias, species.

Genus M.oudia, species.

Genus Laprophyta, species.

Genus Saprolegnias, species.

Genus Enterobryum, species.

Genus Eosinum, species.

Genus Nicotiana, species.

Order II. Cryptogaealogae.

Family Oscillatoria.

Genus Oscillatoria.

Genus Zygnema crassitudum.

Order II. Coniopteridium.

Family Chlorella.

Genus Chlorella watermoria.

II. Fenio.

Division I. Arthroporae.

Tribe Tonsilaci.

Genus Trichophyton, species.

Genus Microsporium, species.

Genus Speronema musca.

Tribe Oldieii.

Genus Achorion Schneidinii.

Genus Oidium, species.

Tribe Aspergieii.

Genus Aspergillus, species.

Division II. Trichoracii.

Tribe Cryptocacii.

Genus Dactylichum oogenum.

Genus Botryis Basiania.

Tribe Sporotrichi.

Genus Sporotrichium.

Tribe Isaria.

Genus Isaria, species.

Division III. Cytoporae.

Tribe Cytoporae.

Genus Musco Musco.

Division IV. Chiroporae.

Tribe Conioptidea.

Section Paragrandes.

Genus P. Assisi fava.

Sub-Division Endoliveii.

Section Sphorhama.

Genus Lobostoma, species.
I. Man and the Mammalia.

A. The Skin.

Trichophyton tonsurans. Malston. (On Hairs.)
T. sporuloids. Ch. Robin.
T. ulcerans. Ch. Robin. (On Ulcerated Skin.)
Microsporum Audouini. Gruby. (Hair Follicles.)
M. matogastieus. Ch. Robin. (Roots of the Hair.)
M. furfur. Ch. Robin. (Skin.)
Mucor mucado. Linnaeus.

Achomorh Schamellein. Remak. (The Hair and the Hair Follicles.)

Aaspergillus species. Facini and Meyer. (Auditory Passage.)

Puccinia farif. Ardsten.

B. On the Mucous Membrane.

Cryptococcus sereus. Kützing. (Intestines.)
C. guttulatus. Ch. Robin. (Rabbits.)
Merismopedia ventriculi. Ch. Robin.
Leptochirax lusca. Ch. Robin.
Oncidium (i) of the Intestines. Ferrer.
Leptomitus urochloris. Mont. (Bladder.)
Leptomitus of Hannover. Ch. Robin. (Pharynx and Oesophagus.)

Leptomitus of the Spidermilia.
Leptomitus of the Uerons.

Leptomitus of Uterine Mucous.
Leptomitus of the Eyes.

Oidium ulicicnus. Ch. Robin. (In Thrush.)

Eggs. of the Lungs. Bennett.

Eggs. of the Nasal Mucous.

II. Birds.

A. Of the Respiratory Organs.

Aaspergillus candidus. Michele. (The Air-Cells and the Lungs.)
A. alabaster. Fries.

A. nigrescns. Ch. Robin.
A. strix nyctea. J. Müller and Retzius.
Moldiness of the Lungs of the Jackdaw. Meyer.

B. The Eggs.

Oxychlamys ogenus. Montague.
Sporotrichum (Nematogonum) brunneum. Schenk.

III. Reptiles.

A. The Eggs.

IV. Batrachians.

V. Fishes.

A. The Skin.

Zygmena cruciatus. Agardh.
Chesnotera (Tremella) meteorica. Ehrenberg.
Saprolegnia ferax. Kützing.

Converse of Gold-Fish. Bennett.

Algae of the Stickleback. Manicus.

A. The Gills and the Cellular Tissues.

Pentacapsulata of the Fish. J. Müller.
P. of the Symodon Schal. J. Müller.
P. of the Sandre. (Luciperca sandra.) J. Müller.

P. of the Bocah. (Cyprinus rutilus.) J. Müller.
P. of the Lobo nitidus. J. Müller.
P. of the Pimodous Blochii. J. Müller.
P. of the Pimodous Sebe, and of Platysoma fasciata. J. Müller.

P. of the Cutamone atalis. J. Müller.
P. of the Odogus elatissus. J. Müller.
P. of the Aerina vulgaris of Grenville. Creplin.

P. of the Scena umbra. Ch. Robin.

VI. Insects.

A. On the Elytra, and on the Articulariae.

G. vivaria. Ch. Robin.

Silbum lupus. J. Müller and Ch. Robin.

B. On the Caterpillars and Chrysalis in the Tissues.

Genus Spharia. Haller.

Section Cordyceps. Fries.
Spharia militaria. Ehrenberg.
S. sphaerocephala. Klein.
S. entomorhiza. Dickson.
S. echteris. Hill.
S. hoberi. Hooker.

Kerdospernum microphalasum. Wallroth.

K. micranthum. Wallroth.

Tsarica deuteruromerus. Nee.

J. acoos. Fries.
J. atrypopsis. Fries.

J. arachniopila. Dittmar.
J. leprosa. Fries.
J. Turtaria. Wallroth.

I. ceraspe. Pernoon.

S. phaeoptila. Dittmar.

J. xenops. Fries.

I. aranearum. Schweltz.

I. mykynum. Schweltz.

I. gigantes. Montague.

C. In the Intestines.

Molluscs of the common. Ch. Robin.
M. octonia. Ch. Robin.
M. gyrin. Ch. Robin.

Leptochirax inclusorum. Ch. Robin.

Genus Sorex. Leidy.

E. longa. Leidy.

E. moniliformis.

Cistolophyrus somatidis. Leidy.

Antheromitus cristatus. Leidy.

A. nitida. Leidy.

VII. The Myriapoda.

A. In the Intestines.

Enterobrya elegans. Leidy.
E. spiralis. Leidy.
E. attenuata. Leidy.

J. ocellata. Ch. Robin.

VIII. The Mollusca.

A. On the Vesicle of Sugs. (Algus indeterminata. Lebert.)

The most interesting of these species are undoubtedly those which attack man or the animals which he domesticates and employs. With the exception of the Botrisa of the silk-worm, the latter have not been much investigated. Those which attack man, and accompany diseased conditions of his body, are better known. They may be divided into those which are found on the skin, and those which are attached to or found in the secretions of the mucous membrane.

1. Entomoptera of the Skin.—Ten species have been noted in this locality. We shall enumerate them in the order in which they are given by M. Robin.

1. Trichophyton tonsurans (Malston); Trichomycetes tonsurans; Myxomera of the Picea Polonica; fungus of the hairs in Herpas tonsurans; fungus of Porrigo sevararia; Achorion Lebertii; fungus of the Teigna tonsurans, Bain; Batropylax, Gruby. This fungus was discovered and described in 1844 by Gruby in the disease called by the brothers Muller. Teigna tonsurans; by Cazeneve Herpes tonsurans; by Erasmus Wilson Trichomes furfuracea (one of the diseases called Ringworm and Porrigo eccutula in this country). It exists also, as pointed out by Gunsberg, in the Picea Polonica, although the two plants were formerly described as different. The Trichop Consultant is formed by oval transparent spores, which give rise to articulated filaments. Its anatomical seat is in the interior of the roots of the hairs. The hairs and fungi simultaneously increase. The format seem larger than usual, are paler in colour, lose their clas-
tightly, soften, and break off when they have risen some one or two lines above the surface of the scalp. In the short course then left the fungus grows still more rapidly, so that the trunk leaves the hair, and sometimes becomes indistinguishable. Sometimes the hair breaks off before emerging from the skin, and the fungus, epidermis, and sebaceous matter, fill the ends of the piliferous conduits, and the hair becomes a naked eye in this disease, and give the skin a rough appearance.

The sporules and mycelium of the plants can sometimes be seen, in the form of a white powder, on the roots of the broken hairs. Sometimes the cutis becomes congested and red, and so thickened with scales of epidermis, with fatty and albuminous granules, with pus, &c., and crusts are formed of greater or less thickness in which the growth of the fungus can go on. Messrs. Robin and Bazin adopt unreservedly the opinion that the Trichophytia is the cause of the disease. It makes the diagnosis of the disease; in the trichophytia of the several species. Each has been named and given, and each has given examples of the con
tention of the disease by the transmission of the spores. Bazin has made the very important observation that the same disease will attack horses, and can be communicated from them to men. Both Robin and Bazin however admit that there is some condition of the hairs (dependent no doubt on constitutional causes) which is essential for the growth of the plant, as sometimes the disease disappears, the hair is dark, hard, and thick, and the affection is not to be seen except in the case of one of the commonest fungus which is the true, and in many cases there are no vesicles at all throughout the whole course of the disease. The term used in this country for Puccinia scutulata is inadvisable as it is applied with greater justice to Favus. The old term of Tinea is given by another, and the specific active tinea expresses well the feature of the disease, the baldness arising from the brittleness of the hairs.

2. Trichophytia (? sporusculata) (Rubin), (Myoderm of the Plica Folliculus). In addition to the former species, Walleriana has been described. The circumscribed flattened spores, which have been too little studied to be stated to present their exact characters to be stated.

3. Trichophytia (? ucercum) (Rubin). Lebert has described a fungus in the crusts covering an aciculous nodule of the bear.

4. Microsporon Audouini (Gruby). This mycelium has been studied by Gruby, and its existence, though denied by Cazenave, has been confirmed by Robin. It is present in the disease commonly called after Willan Puccinia desiccativa or Puccinia scutulata. It differs from the Trichophytia of Tinea tondens, by its numerous waved filaments, and by the extremely small size of its sporules. It is not found, like the Trichophytia, in the interior of the root, but forms round each hair a little tuft of the same, somewhat similar to that of the Alsect. The Aleocia is rapid, with or without vitiligo of the skin. The dermis is not congested, and the epidermis is thin and smooth. There is an affection which should probably be distinguished from the Puccinia desiccativa, or Alsect. coronscripta, and which is characterised by a rapid disappearance of pigment from both skin and hair, with or without Aleocia. M. Bazin includes it in his Tinea achromatosa, but does not mention the fact that Aleocia is not constant. He states that a parietal plant is present, but does not describe it. There must however be something more than a fungus to cause the total disappearance of pigment from a considerable portion of the dermis. Besides, when the hairs return they sometimes appear only greyish or thin colored, and if the vitiligo were on the root of the plant, it is pro
bable they would not grow at all. The disease appears to be allied to those obscure pigmentary changes which have a much deeper seat than the surface of the body.

5. Microsporon furfur (Rubin). In 1846 Eichstett discovered a cryptogamic plant in the disease called by Willan Puccinia varicale, and more lately Alopecia. Soon after-
Tinea faciosa can be communicated by transfer of the plant, and that the disease can be cured with the greatest readiness by the application of a preparation of the bark of a plant more or less destructive to vegetable life. That a special nidus is necessary may very well be admitted by the partisans of this view, since even in the case of epidemic agents a predisposition is necessary; yet no one dreams of confounding the co-operating cause with the special and peculiar poison.

It may be desirable to recapitulate the diseases of the skin in which parasitic plants are found:—

1. Tinea tondu in which the Triphophyton tondu is present.
2. Tinea faciosa, in which are present the Acchorion Schencklinii, and the Pustecini Favei in some cases.
3. Mentagra, or Tinea mentagia, which exhibits the Microsporon metagraphi.
4. Neuitis fulvus (Chloasma), in which the Microsporon furfur occurs.
5. Perrigo decalvans (Tinea achronatmos), in which the Microsporon Audouni is found.
6. Pilo Polonem, in which the Triphophyton tondu and Triphophyton sporidoriae are present.

11. Entophyta on the Mucons Membrane.—The plants forming on mucous membranes, or in the contents of cavities lined by mucous membrane, are of less interest than those which occur on the skin, as in most cases they are decidedly only secondary. We shall merely enumerate them:—

1. Cryptococcus Cerviica, Knitting (Torula Cerviica), the Yeast-Plant in the bladder, stomach, intestines, &c.
2. Merismopodia senescens, Robin (Cervinae), in the stomach of the horse and other animals.
3. Leptokaria buccalis, Robin (Alga), of the month.
4. Octularia of the intestines. (F. Par.)
5. Leptosynera urispinus, Robin; an Alga described as forming in the nines. It has as yet been scarcely studied.
6. Leptosynera (T.), Hanover, Robin; Alga found by Hanover in the pharynx and esophagus.
7. Leptosynera of the uterus.
8. Leptosynera of the uterine mucus. (E. Han.)
9. K. M. (F.)
10. Oidium albicans, Robin (Cryptogenic) of diptheritis and aspas; Aptophyte. (Gruby.)
11. Fungus of the lungs. (Bennett.)
12. Fungus in the discharge of glands.

To this list from M. Robin may be added the so-called Cholera Fungus of Brittan and Budd. It should however be added that no confirmation of the view originally taken by the discoverers, that the fungus discovered in the dejections of man with cholera, is the cause of the disease, has been afforded. The only explanation that can be given of the occasional occurrence of the spores of fungi or spore-like bodies on the mucous membrane of the stomach and intestines, is their introduction with the food. It has been shown that spores of certain fungi are found naturally on grains of wheat, and only await favorable conditions for development. Such fungi may be constantly introduced into the stomach with the floor of wheat in the form of bread or other kinds of food.

Is the study of the vegetable parasites of animals, particularly those of the intestinal canals, it is necessary to be careful not to confound the tissens of certain well-known cryptogamie plants, which may serve as food or adhere to the ordinary food of such animals, with true Entophyta. Thus fragments of fungi, convery, lichens, and the spores of these, need as food, or adhering as foreign matter to food of an ordinary kind, are liable within the intestine to be mistaken for the vegetable parasites of animals.

In mid-winter I found beneath an old fence- rail an individual of Aschera nigra, or large black cricket, within the provisions of which were large quantities of what I supposed at the time to be a free floating Entophyta, resembling in general appearance the ordinary Yeast Fungus or Torula, but which I now suspect to be an ergot upon which the animal had fed. The plant consisted of oblong or oval vesicular bodies, apparently thickened at the poles, and filled with a white material, but this appearance more probably arose from the cells being condensed together in a single large, transparent, colorless, amorphous globule, which pressed a small existing amount of protoplasm to each end of the cavity. The cells were single, or in rows, to eighteen in number, and in some single cell of comparatively large size had an attached pair of cells, or rows of cells at one or both ends. Occasionally they are met with containing one or two small round hyaline amorphous nuclei. The isolated cells, measured from the 20th to the 40th of an inch in length, are about 30,000 to the inch, and the rows measured up to the 60th of an inch in length. (Leidy.)

ENTRE RIOS, one of the Riverin provinces of the Argentine Confederation, South America, owes its name to its situation, which is at the mouth of a river named Parana. Its boundary comprehends however only the southern part of the peninsula formed by those rivers, the northern portion forming the province of Corrientes. The boundary between the provinces is formed by the Rio Guaycuruque, which falls into the Parana near the town of Mocoreta, which lies between 30° 30' S. lat. The area is about 23,000 square miles. The population is about 25,000.

This surface is gently undulating; it is broken by hills along the middle portion or interior of the country. The part is covered with forests of low stunted trees. The southern part of the province is low, and especially along the banks of the Parana subject to inundations. The northern part is occupied by a low swampy tract, known as the Forest of the Immortelles, a term which was given to it by Audouin. The province is abundantly watered by numerous small streams. The soil of Entre Rios is in general fertile, and covered with luxuriant herbage. The climate is mild and dry. Frost never occurs, the lowest temperature seldom falls more than fifty days in the year. The highest range of the thermometer during the year 1844-47 was 96° in January 1844; the lowest, 50°, occurred in the month of June in 1844 and 1846. (M'Cann.) Cultivation is limited to a comparatively few spots. The principal grain crops are wheat, barley, and maize. Tobacco and cotton of excellent quality are also raised, but the crops are precarions in consequence of frequent droughts. Great damage is also done to all kinds of crops by the immense swarms of locusts and ants, which sometimes descend like a rain upon the country.

The banks of the Parana during the year 1844-47 was 96° in January 1844; the lowest, 50°, occurred in the month of June in 1844 and 1846. (M'Cann.) Cultivation is limited to a comparatively few spots. The principal grain crops are wheat, barley, and maize. Tobacco and cotton of excellent quality are also raised, but the crops are precarious in consequence of frequent droughts. Great damage is also done to all kinds of crops by the immense swarms of locusts and ants, which sometimes descend like a rain upon the country.

In 1844 so great a drought occurred that the grass was everywhere burnt up; and Mr. M'Cann states that the whole of the cattle in the province went off from the feeding grounds during the drought. The cattle has, however, since then been increased from 40,000 to 50,000, and now numbers 150,000. Horses are bred in great numbers. Owing to the long-continued state of anarchy in the province there are, in the unsettled parts, numerous herds of wild cattle and horses. The people are generally small; many of them are Indians or mestizos of mixed blood.

Mechanical employments are almost entirely neglected. The geographical position of the province admirably adapts it for commercial pursuits; but owing to the many of the country, living with Corrientes in the same large, disturbed state in which the country has so long been kept comparatively little commercial progress has yet been made. Now however that the rivers are declared open to vessels of all nations, under the guarantee of the principal maritime powers, there seems to be required only internal peace for the development of the great capabilities of the country. The exports are principally of hides, corns, tallow, and jerked beef.

Like the other provinces of the Argentine Confederation, Entre Rios is a feudal state, owning but little dependence upon the central government. The government is almost entirely in the hands of a governor, elected for the term of two years. The Congress consists of deputies chosen from the several towns or districts. The revenue is derived chiefly from customs duties.

Except a few families of Guarani origin, the country is almost entirely inhabited by the descendants of Spaniards. In the towns however a few foreigners are settled, mostly Italians, and a very few of Scotch and of some French and English traders. Some of the large estancias (cattle farms) and saladeros (tallow-melting establishments) are the property of and conducted by Englishmen.

Entre Rios took a leading part in the revolt against the soldiery of the Ayres, joining with Corrientes in the engagements with foreign powers, which led to the fall of Rosas, and in
**Concepción de la China,** formerly called Uruguay city, on the Uruguay, is a small but old town of about 1500 inhabitants. It once carried on some trade with Montevideo, but it is now decayed and ruinous. The houses are mostly built of wood and mud, with thatched roofs. In the centre of the Plaza is a pyramid now falling to pieces. In the vicinity is a large saladero. **Concordia,** on the Uruguay, opposite Salta, from a village of a few mud huts, appears to be growing into a town of about 1000 inhabitants, and carries on a good deal of trade. But the situation is bad, as vessels are unable to reach the town at low water, and are obliged to anchor about two miles below it. It contains a church and a large school-house, endowed by the government, on the model of those in the same name (31° 10' S. lat.), is a town of between 2000 and 3000 inhabitants, of whom nearly 300 are foreigners, chiefly Basques and Italians. It is a place of a good deal of trade, but vessels cannot approach nearer than about three leagues from the town. In the neighbourhood is the most extensive estancia in this part of the country, belonging to an English subject. It is the property of Mrs. Britannia of Sheffield, and occupies 500 productive leagues of land. Several other estancias belong to the British, and which are worked by negroes, near the month of the Gualeguay-chu, about 60 miles E.N.E. from Gualeguay, population about 2500, including nearly 300 foreigners, contains a neat church and a good school-house, and is a place of some trade; but the situation is inconvenient, as vessels drawing more than 6 feet of water are sometimes obliged to wait two or three weeks to get across the bar at the mouth of the river. In the neighbourhood are some large tallow-melting establishments.

**Epera,** a genus of Plants belonging to the natural order **Paceae.** It has four thick and concave sepalae connected together into a permanent urceolate tubule at the base, with the segments inserted at the side. The flower is a perfect one petal, which is roundish, fringed, and inserted in the middle of the calyx. There are 10 stamens, which are long thickened filaments, rather villous at the base, and joined into a short monadelphous ring. The ovary is stipeate. The style long and filiform. The legume compressed, dry, coriaceous, falciform, 2-valved, 1- to 4-seeded. When young it is tomentose. **E. falcatia** is a tree with abruptly pinnate leaves, bearing 2 or 3 pairs of ovate acuminate leaflets on peduncled, constantly composed of numerous distant racemes. It is the Wallaba-Tree of Guyana according to Sir Robert Schomburgk, who informs us that its wood is deep red, frequently variegated with whitish streaks, hard, heavy, and shining, and impregnated with an oily resin which renders it very durable. It is bark is thicker, and is used by the Arawak Indians as an emetic.

**Equisitite.** [Mineralogy, 21]

**Equidae.** [Mammalogy, 6]

**EQUITY.** The proceedings of the Court of Equity have been greatly simplified and cheapened by several recent statutes. The nature and objects of the jurisdictions of the Commissioners appointed to examine this subject in 1850. Instead of the writ of **suppensa**, which merely gave the defendant notice of a bill having been filed but afforded him no information of its contents, the bill itself, in a convenient printed form, is now served upon the defendant, either personally, or by being left at his house; or under special circumstances with some other person (as for instance, the solicitor or agent of the defendant) as his substitute.

In the case of an attachment against an unprivileged person, by having an attachment issued against him; against a privileged person, as a peer, or member of parliament, by a sequestration of his property; against a corporation, by a distrain and sequestration if necessary. In the latter, on the giving of a bond, the Court need only on the prosecution by way of attachment and sequestration, he may enter an appearance for a defendant not appearing within eight days after the service, and thenceupon proceed to judgment, and execution.

Until the recent alterations, every bill in chancery contained what is called the **interrogating part** in which every statement and charge in the bill was converted into a series of questions, framed on the principle that the defendant might possibly be a dishonest defendant, disposed to answer evasively, and therefore suggesting modifications of the statement or charge. For example, if the statement were of a deed bearing a certain date, and made between and executed by certain parties in certain words, or to a certain effect, the questions would be, whether such a deed of that date, or of some other and what date, was not made between and executed by such parties, or some and which of them, or some other and what parties, in such words, or to such effect, or in some other and what words. Originally these interrogatories were used much more sparingly, and they were confined to those matters supposed to be within the knowledge of the defendant, as to which it was considered necessary or desirable to extract admissions from him. But in many of the actions with which the old practice was still lived the process was adopted of transmuting all the statements into questions of the nature above described. The length of the proceedings and the expense to all parties concerned were thereby greatly increased. There is now no interrogating part in any suit, and where a defendant, whether from any defendant or to a bill, he may file interrogatories for their examination.

The demurrer, plea, or answer of the defendant to the bill, each remaining as before, is no longer taken with the expensive formalities which used to accompany it. Formerly a *decimus potestas* or commission was issued to take the answer and oath of a defendant in the country, which was scaled up, and either brought by one of the commissioners to the county, or sealed the defendant, who swore he received it from one of the commissioners, and that the same had not been opened or altered since he received it. The answer is now however filed without further formality than in swearing to affidavits, and unless sworn before any justice of the peace, a public, or vice-council, lawfully authorised to administer oaths, the messenger's oath being dispensed with.

In many cases, indeed, when the facts in dispute between the parties are not of a complicated character, the answer is now not requisite. Affidavits may be filed by the plaintiff and defendant, upon which the court will determine the case, unless it be thought proper, in addition thereto, to examine or cross-examine the parties orally.

The practice which formerly prevailed of examining witnesses on interrogatories, having been found in many respects very inefficient and objectionable, has also been abolished; the court retaining the power to order particular witnesses to be examined on oaths or by affirmation. The exceptions allowed are as before.

When therefore a suit commenced by bill is at issue, the plaintiff may give the defendant notice of the mode in which he desires the evidence to be adduced, namely, orally or upon oaths; and if either party give no such notice, or if giving such notice, he expresses his desire that the evidence be adduced upon affidavit, then both plaintiff and defendant may verify their respective cases by affidavit, unless the defendant gives notice to the plaintiff that he desires the evidence to be adduced orally. If no such notice be taken, the witnesses are examined by or before one of the regular examiners of the court, or an examiner specially appointed if necessary. The principal defect in the old mode of examining witnesses was, that the examination being oral, and in many cases conducted by the parties being conducted in the same manner, the party cross-examining laboured under the disadvantage of not knowing what the witness had deposed to his examination in chief; under the modern system, the oral examination of witnesses takes place in the presence of the parties, their counsel, solicitors, or agents;
and the witnesses are then and there subject to cross-examination and re-examination. Every deposition is taken down in writing by the examiner in the form of a narrative, and read over to the witness, and signed by him, in the presence of the parties. When concluded, the examiner transmitted the depositions to the Court, and the cause is then ripe for the hearing.

Another important change in equity procedure relates to the determination of questions of fact, as distinguished from equity. Formerly, if a question of fact arose in the course of the practice of the Court to refer it to the opinion of the judges of the Courts of Common Law, upon a case stated for that purpose; who certified their opinion to the chancellor, upon which certificate the decree would be made. Now the judges have determined and are to settle any questions of law which require to be decided previously to the decision of the equitable question at issue between the parties; for which purpose any of the courts may obtain the assistance of the judges of the Courts of Common Law.

A shorter and simpler method of proceeding than that by Bill and Answer was introduced in the year 1850, namely, that of Claims. This plan was only intended to be used in certain definite cases of comparative simplicity; and subsequent legislative enactments have so much improved the mode of proceeding by Bill, that the advantage of having recourse to a Claims is not now so great as when that procedure was first introduced, and in many cases a Bill according to the new system is found to be preferable. Claims are indeed nisi prius pleadings in the old sense, with the merits of which are to be decided upon affidavits on each side; every order made on the hearing of which has the same effect, and may be enforced as a decree in a suit commenced by Bill. Orders made on claims may also be discharged, varied, or altered, as in the case of the Writ of Habeas Corpus in Chancery, or of the Rolls, or any of the Vice-Chancellors, may be discharged or varied by the Lord Chancellor or the Court of Appeal in Chancery.

A still more summary method of proceeding has been introduced, by the statute 15 & 16 Vict. c. 86, applicable to similar cases of administration. Any person claiming to be a creditor, legatee, or next of kin of a deceased person, may obtain a summons from the Master of the Rolls or any of the Vice-Chancellors, requiring the executor or administrator of the deceased person to attend and show cause why an order for the administration of the estate of the deceased should not be granted.

Upon proof of the due service of such summons, or on the appearance of such executor or administrator, and upon proof by affidavit of such other matters, if any, as the judge shall require, the judge may make an order for the administration of the estate of the deceased, with such variations, if any, as the judge shall think fit. This order is to have the force and effect of a decree to the like effect made on the hearing of a cause or claim between the same parties.

A special case may also be filed, in order to obtain the opinion of the Court upon the decision of any question under Sir George T usher's Act, 13 & 14 Vict. o. 35; but as the Court can now make a merely declaratory decree, under 15 & 16 Vict. c. 86, the same end may be more conveniently obtained, in most cases, by a short Bill without interrogatories.

These are the principal alterations in the procedure of our Courts of Equity; some minor details of practice in which changes have been effected, it would be out of place to enlarge upon.

ERICSSON, JOHN, Engineer, a native of Sweden, but whose inventions have been brought before the scientific world in England and America, was born in the province of Vemeland in 1803. In 1814, by the friendship of Count Platen, who observed his mechanical tastes, he obtained a cadetship in a corps of Engineers. He subsequently entered the regular army as an ensign, and at length reached the rank of lieutenant. In 1826 he visited England in order to bring into notice a new kind of engine which he had invented, and worked at the Whitehall, by the withdrawal of the sensation of flame. The project failed from the impossibility of procuring suitable fuel for the engine. He competed for the prize which was offered by the Liverpool and Manchester Railway Company in 1829, for the production of the best locomotive engine, and was the first to run an engine at the rate of fifty miles an hour. Ericsson's subsequent career lay chiefly in America. In the Great Industrial Exhibition of London in 1851, several instruments for the measurement of distances at sea, for measuring fluids under pressure, and other similar purposes, appeared in the American department under Mr. Ericsson's name, and were described by him in a small work which he issued at the time. His name is chiefly known in connection with a project for a caloric engine, a British claim to the use of an object which, if accomplished would, by removing the necessity of carrying large cargoes of fuel, have effected a great commercial change in the intercourse between distant parts of the globe. As the project is a difficult one, it is probable that the British government referred its consideration, Mr. Ericsson tried it in America, and obtained sufficient co-operation to enable him to launch a vessel named after himself, and measuring 2000 tons. This vessel made a trial trip under steam in 1853, and then stopped short, and on his return she was struck by a squall, filled, and foundered close to the city of Jersey. The Ericsson was subsequently raised, and the caloric engine was replaced by a steam engine, which possessed some improvements devised by Mr. Ericsson. Mr. Ericsson was a member of numerous scientific societies and a knight of the Swedish order of Vas.

He died on the 2nd of November, 1863.

ERINITE. [Mineralogy, § 1.]

ERROL. [Parishes.]

ERROR, IN LAW. The mode of appealing from the judgments of the Courts of Common Law to the appellate tribunals constituted to rectify their mistakes by bringing error to their attention, is prescribed by the Common Law Procedure Acts of 1853 and 1854. These statutes have abolished writs of error in civil suits, and substituted for them a simple notice or memorandum of error, to the opposite party and to the Court, of the appeal having been given in. The practice is, that the writ of error is issued, and in so doing improved the jurisdiction of the Courts of Error. Formerly judgment could only be affirmed or reversed; but the Court of Error now give the judgment which was given below, and award all necessary process for giving effect to it.

ERYTHACA, a genus of Birds belonging to the family Sprotidae, the order Passeres, having the following characters:—Beak rather broad and depressed at the base, becoming narrower towards the point, and slightly compressed; upper mandible deflected and notched. Nostrils basal, lateral, oval, pierced in a membrane partly hid by feathers and hairs projecting from the base of the beak. Wings rounded; the three exterior quills graduated; the first only half as long as the second, which is shorter than the third; the fourth, fifth, and sixth longer than the third; the fifth the longest in the wing. The tarsus longer than the middle toe; the lateral toes nearly equal to each other is less than the middle. The wings with the claw of the hind toe longer and stronger than the others.

E. rubecula, Sylvia rubicula, Motacilla rubecula, the Robin Red-Breast, Robin-Redstart, Robinett, Roodlock, is so generally distributed over the British islands, and so universal in its habits, that all are sufficiently interested in its nest, to make themselves acquainted with its habits. These may be observed in any garden, field, or wood, for there is scarcely a hedge without its Robin inhabitant, and if Robins appear to be more numerous in winter than in summer, it is partly owing to the state of vegetation at the former season, which leaves them more exposed to observation, and partly because they resort to the habitations of men for food, when other means of supply fail. The song of the Robin is sweet and sensuous, but not very agreeable, as Selborne says, "The Robin sings all through the year. The reason that he is called an autumn singer, is, because in the spring and summer his voice is lost in the general chorus, while in the autumn it becomes distinguishable."

The Robin is one of the first to return, and the earliest to be seen moving in the morning, requiring apparently but little sleep."

This bird is very easily tamed, soon becomes familiar with those who feed it, and constantly builds its nest in places frequented by man.
other, and many instances have been related to prove that they pair for life. With all his interesting qualities the Rattle-tail proved a skilful fowl, and not only maintains his right against all intruders, but is said to kill those of his own family when they become troublesome to him. Robins breed early in the spring. The nest is composed of moss, dead leaves, and dried grass, lined with hair, and is generally placed on a bank or tree. It is frequently placed on a bank sheltered by brushwood, or a short distance above the ground in a thick bush or lane hedge, sometimes in a hole of a wall partly covered with ivy. The eggs are from five to seven in number, white, spotted with pale reddish-brown; the chicks, when hatched, are mostly covered with down, and the throat, and the upper part of the breast, reddish-orange; encircling this red is a narrow band of bluish-gray, which is broader near the shoulders; lower part of the breast and rear of the neck more brown; and under tail-coverts, pale brown; under surface of wing and tail feathers dusky gray; legs, toes, and claws, purple brown. The whole length of the bird is 6½ inches. The female is not quite so large as the male, and her colours are less bright. The young birds, after their first autumn moult, resemble adult females; but the red of the breast is tinged with orange, and the legs are dark brown. The Red-Breast is subject to variation in the colouring of the plumage. White and partly white varieties are rare.

(Yarrell, British Birds; MacGillivray, Manual of British Birds.)

ERYTHRIGIC ACID. [Chemistry, S. 2.]

ESTHALIAD, a genus of Birds belonging to the Passerines. The species are known by the name of Waxbills. They inhabit the Indian Archipelago and Australia.

ETYLL. [Chemistry, S. 2.]

ETYLL at the College of Physicians was born on York, March 10, 1767. His father rented a mill in the suburbs, and kept a baker's shop in the city; and the boy assisted in the shop till he was of age to be put to learn a trade. He had already shown a marked fondness for drawing, and his mother, as in after-life the great painter was fond of relating, had encouraged his propensities, while neighbours used to 'patronise' the inquisitive child with halfpence and pennies to buy chalk and pencils. In his twelfth year he was apprenticed to a painter at Hull, in which situation, over-worked, without friends and distant from his family, and denied the privilege of drawing, he appears to have at first led a very uncomfortable life. But after awhile his master was persuaded to let the boy 'at lawful hours' indulge his artistic tastes, and, though still without instruction, Etty soon began to acquire sufficient facility in drawing to make his companions in the painting-office desirous to possess, and some of them careful to preserve, his sketches and rude attempts at painting. At length, his seven years' apprenticeship having expired, he gave himself over to the pursuit of art to come up to London. His uncle, himself a skilful draughtsman, saw promise in the youth's erudite tastes, and generously afforded him the means of practically solving the question whether his inclinations were to be indulged or a profession was an impulsive move or the result of a native aptitude. At first, without any formal instruction, he drew, as he says in his 'Autobiographical Sketch,' 'from prints, or from nature, or from anything he could...his first academy being a plaster-cast shop, kept by Gianelli, near St. Paul's.' Having thus sufficiently mastered the difficult-
EUNICE, the property of the Royal Manchester Institution. In the Vernon Gallery are eleven paintings by Etty, of which the chief is his 'YOUTH at the Fow and Pleasure at the Helm,' and in the Shepherds Gallery are two others.

Etty is undoubtedly one of the greatest names in English art. He chose for himself a somewhat remarkable path, and in it he walked without a rival. His want of classical education—learned by himself mostly from Linschmidt's Dictionary—together with his deficiency in every kind of intellectual culture, except in the techniques of painting, of course militated against his taking a first rank as a painter of classic themes. All his works evince his having been a good academician, but his style has been influenced even with the poetry of Greece and Rome. But, allowance being made for these deficiencies, or rather regarding his pictures as the mere vehicles for the exhibition of the undraped human form, his paintings must be allowed to occupy a very high place in comparison with those of any other modern painter.

To the highest order of female beauty either in face or form he never attained—hardly pretended; yet there is nothing in his pictures to show that the artist was always conscious of a want in that respect. He knew too, and he had the confidence to feel, that art will make up in beauty what it lacks in the other qualities of life. If he had desired to be the painter of small girls, as he was, or the painter of young novices, or the painter of matronly ladies, he might have painted them with that grace and enjoyment, so much life and heartiness, and, looking at them as pictures, there is shown so remarkable a knowledge of the female form, and such facility in rendering it in free spontaneous action, as few if any modern artists of any country have equalled, and none even in olden times passed.

Etty towards the close of his life seems to have become especially disturbed by the strong remarks occasionally made on his choice of subjects, and still more on his mode of treatment. He was often referred to as a "painter of girls," as it has been spoken as though they thought so too, that the objections raised to so free a display of the female form on the score of morality, was in fact an implication that the painter was手册 of Mollusca belonging to the family Pyrnellidae, founded by E. Forbes, to receive forms that had not been previously referred to Eubranchiis and Odontocreats. The shell is elongated, and consists of many whorls, smooth, and polished; the apex of the spine has a persistent embryonic sinistral shell; the aperture subquadrate; peristome cartilaginous; columella not plaet, straight nearly so; operculum corneous, pyriform. There are four British species. E. solis (Eutima crassula, Jeffrey), E. acuta (Mollusca acuta, Philippi), E. affinis (Eutima affinis, Philippi), E. charis (Turborina cedrosa, Loven).
EUPATORIA, previously named Kostaf, a sea-port town in the government of Taurida, on the western coast of the Crimea, is situated on the north shore of the Bay of Kalmius, in about 45° 14' N. lat., 33° 25' E. long., 40 miles N.W. from Simpheropol the capital of the Crimea, and 46 miles N. by W. in a straight line from Sebastopol. There was in 1890, chiefly Tartars and Karaitic Jews, with a few Greeks and Armenians.

The port is shallow, allowing only vessels of about 8 feet draught, but tolerably safe and never frozen up. The bay fronting the town contains a number of islands, which may approach within cable's length of the shore, but it is exposed to the west and south winds which cause a heavy surf all along the coast.

The town, which is surrounded by an old crumbling wall, is ill built; the streets are narrow, crooked, and dirty; the houses, low and built of bricks and clay, open upon courts or gardens in the Turkish fashion, but present to the street only dead walls.

The principal buildings are a Russo-Greek church, several mosques, an Armenian church, two pretty synagogues belonging to the Karaitic Jews, a hospital, and the house of the governor, on the heights, surrounded by the district.

The principal industrial products are leather, felt stuffs, and wood-work. The town is famous for the preparation of the black lambkins, known in England as 'blacks' for the inland and foreign trade, with which it is the southeastern coast of the town on which a good deal of salt is gathered in summer.

The water in the town and neighbourhood is bad. Before the Russian occupation of the Crimea, Eupatoria, it is said, had a population of 30,000, and was the centre of all the export trade of the coast. In order to restore the prosperity of the place it was made a free port for a limited period from the year 1798, and its trade partially recovered, but subsequently dwindled away on the rise of Odessa. It still remains of importance in salt, corn, flour, hat, iron, leather, hiders, hatter, wax, hair, linen, etc. There is a quarantine station at Eupatoria.

Eupatoria is said to occupy the site of the ancient Eupa-toria, or Eupatoriensis, founded by Mithridates Eupator, and named after him. The Russians call it Eupatoria, but this is no proof that the two places are identical. Some authors say that the site of the ancient Eupatoria is marked by the village of Inkerman on the north shore of the Bay of Sebastopol, where there are ancient ruins. Be this as it may, Eupatoria was destroyed by Nadar in 1377, the Tartars taking possession of it about the year 1761, and then it was occupied by the Allies Sept. 13, 1854, and they held it till the termination of the war, when it was restored to Russia.

EUXENITE. [MINERALS, S. 1.]

EVIDENCE. Great and important changes have been made during late years in the Law of Evidence. Not only have the means of obtaining and producing evidence been simplified, and facilities in doing so afforded to the officer; but all the former disqualifications of the parties to and of the persons interested in the result of the proceedings have been entirely removed. The most important practical improvements have been in our Courts of Common Law, the want of a complete discovery by the oath of the parties having formed till recently one of the greatest and most prominent defects in the procedure of the court. The law has now been extended to allow such a discovery, by going through the expense and circuitry of a Court of Equity, and therefore it was sometimes had by consent, even in the courts of law. But as it had long been established in our Courts of Equity, and as it seemed to be in the interest of justice that it should in the same way be allowed in the courts of record, in the examination of the same facts, a discovery by the oath of the parties should be permitted in some courts, and denied in others, the same power of compelling a discovery was at last conferred on the Superior Courts of England by the 6 & 7 Will. 3 Court of Chancery. A second defect in the procedure of the Courts of Common Law was of a nature somewhat similar to the first; the want of a compulsive power for the production of discovery by the oath or examination of third persons they can generally be obtained by rule of court, or by adding a clause of requisition to the writ of subpoena, which is then called a subpoena duces tecum. But in mercantile transactions generally, the right of the party's own books is frequently decisive; as a matter of course of fixing a bill in equity, an original power for the same purpose was also conferred on the courts of law, by the statute 14 & 15 Vict. c. 99.

This power to compel a party, on the application of his opponent, to produce his books only was exercised, however, where the applicant can satisfy the court or judge applied to, that the document, of which he seeks the production, is in the possession of his adversary. If he cannot do so, his application is rejected; and the only alternative is to institute discovery from his opponent, if he has, in fact, the documents of which inspection is sought, which he is enabled to do by the Common Law Procedure Act, 1854. Upon an affidavit of his belief that any document, to the production of which he is entitled, is in the possession or power of the opposite party, the party against whom such application is made may be ordered to answer, on affidavit, what documents he has in his possession or power relating to the matters in dispute, or whether he has procured or used the custody of such documents, and whether he objects (if so, on what ground) to the discovery of such as are in his possession or power. Upon this answer being made, the court or judge may make such further order as is just; for the party may have the documents, and yet have good cause for withholding them.

Until recently the Courts of Common Law possessed no power of compelling the discovery by one party of facts exclusively within the knowledge of his adversary. Each party may so doubt be called as a witness by his opponent; but this does not always the difficulty for a party of course, if what his adversary will swear, will not, except in the most desperate emergency, put so interested a witness into the box. For the discovery, previous to the trial, of facts as well as of documents, is the object of the act of Parliament of 1854; but to resort to a Court of Equity. The Common Law Procedure Act, 1854, now, however, enables either party, by leave of the court or a judge, to interrogate his opponent upon any matter as to which discovery may be sought, and to require such party to answer the questions, within ten days, by affidavit, sworn and filed in court. By thus affording an opportunity for the examination of the parties upon matters relating to the question in dispute, prior to the trial, facts important for the applicant's case, but exclusively in the knowledge of his adversary, may be discovered and produced, but the trouble and expense of producing evidence of facts which he is prepared to admit may be entirely saved; while such an examination may in some cases tend to make manifest the correctness or falsity of the adversary's grounds, and thus aid to a proper and peaceable litigation.

With regard to parol evidence, or witnesses, the law now bring them in by writ of subpoena ad testificandum, now runs (by statute 17 & 18 Vict. c. 34), into Scotland and Ireland, thus dispensing with the necessity of a commission to examine witnesses, which issues when a witness is abroad, or so ill as to be unable to attend and give evidence.

With regard to witnesses, the general proposition now holds that all witnesses, of whatever religion or country, that have the use of their senses, are to be received and examined, for such are competent witnesses, though the jury from other circumstances will judge of their credibility. The law formerly excluded such persons as were infamous, or were interested in the event of the cause. Infamous persons are such as may not act as witnesses by law, and are excluded from the jury; such as are potential witnesses, from the law. The law has thus expelled not only the parties to the cause, but any one who had the most minute interest in the result; for every person so circumstanced, however insignificant his interest, was presumed incapable of resisting the temptation to perjure; as perjury is the number one crime of every judge, and every judge is a potential perjurer committed under circumstances especially calculated to excite suspicion. But as it is perfectly obvious that any witness who can throw any light upon the subject, should be allowed to appear in court, and the rule is one which observation as might be made, either as to his means of knowledge, or his disposition to state the truth, the stringent rules
of our former law have been gradually relaxed by a series of modern statutes. The first inroad on the systematic exclusion of evidence, which was the result of the former state of the law, was made by the statute 3 & 4 Will. 4. c. 45, s. 66, which has been already mentioned, and is only again referred to for the present purpose. The principle involved is that no man shall be required in order to render the rejection of witnesses on the ground of interest less frequent, if any witness should be objected to as incompetent, on the ground that the verdict or judgment in the suit would be admissible in evidence for or against him, he should nevertheless be examined; but in that case the verdict or judgment should not be admissible for or against him, or any one claiming under him.'

A much greater improvement was, however, effected by the statute 5 & 6 Vict. c. 23, which made it competent for the ground of interest in all persons, except the parties to the suit, or the persons whose rights were involved therein, or the husband or wife of such persons. The advantages found to flow from this alteration in the law led to the statute 16 & 17 Vict. c. 62, which excluded all persons directly interested in the suit) was repealed. By the second section, the parties are made competent and compellable to give evidence on behalf of either or any of the parties to the suit in any court of justice. The third section of the statute provides that it shall not render any person charged with an offence competent or compellable to give evidence against himself, nor shall it render any person compellable to answer an interrogatory in his own behalf, nor shall it render any husband or wife competent or compellable to give evidence for or against his or her husband, nor any wife or husband of such person, without the particular person, that it shall not apply to any proceeding instituted in consequence of adultery, or to any action for breach of promise of marriage. It was decided, soon after it had become law, that the second section of the statute did not render a wife admissible as a witness for or against her husband, and, accordingly, the statute 16 & 17 Vict. c. 53, was passed, enacting that the husbands and wives of the parties to any suit, or of the persons on whose behalf any such proceeding is brought or defended, shall be competent and compellable to give evidence on behalf of either party or any of the parties. Neither husband nor wife is compellable, however, to disclose any communication made or received during marriage; and neither party is a competent witness in a criminal proceeding, or in any proceeding instituted in consequence of adultery. By these several statutes all rules tending to the exclusion of evidence have been abrogated, except in the particular instances above mentioned. (Blackst. 'Comm.' Mr. Kerr's ed. 1756).

EXCELMANS, REMI-JOSEPH-ISIDORE, BARON, Marshal, was a native of Bar-le-Duc, where he was born November 13, 1775. He entered the army very young, and first drew attention to his services, in 1798, whilst under General Poniatowski, in the campaign against the conquest of Naples. In 1800 he became aide-de-camp to General Broussier; but exchanged that for the same post under Murat. At the combat of Wurtemberg, on the Danube, October 6, 1805, he had three horses killed under him; and being commissioned to lay the numerous flags taken from the enemy at the feet of Napoleon I., he received from the hands of the emperor the decoration of officer of the Legion of Honour. On September 18, 1806 he was made colonel of the first regiment of Chasseurs, and was mainly instrumental in the capture of Posen, in Poland. He was afterwards engaged at the doubtful battle of Eylau, and for his conduct in that action (1807) he was appointed to command a brigade, and placed on the staff of Prince Murat, whom he afterwards accompanied to Spain. It was General Exelmans who was commissioned to head the escort by which King Charles was attended to Bayonne, after he had been induced to abdicate in favour of his son. A few days after this special service, Exelmans was arrested, with other officers, by order of the King, whereupon he remained a prisoner until 1811. On his release he again joined his former general, who had ascended the throne of Naples. Sent to Russia in 1812, in Junot's corps, as second in command, and having distinguished himself at various times, he was created a general of division, September 8, 1812. Savary, in his 'Memoirs,' ascribes entirely to Exelmans the merit of saving the remnant of their corps, which returned home after that arduous campaign.

In 1813 his division was placed under the orders of Marshal Macdonald; he took an active part in the operations in Saxony and Silesia, and was rewarded with the cordon of great officer of the Legion of Honour. In 1814 he commanded the cavalry of the imperial Guard, and was made a general of division by Napoleon to defend the French territory. After the return from Elba, General Exelmans was called to the Chamber of Peers, June 3, 1815; and despatched to join the army of the north. He was not present at Waterloo, but he had the honour of returning back his division to the walls of Paris, in time to defend the capital, and to check the advance of the Prussians, whom he defeated at Vernailles in the last action of the war. Exelmans was included in the decree of July 24, 1816, and banished from France with many others, but after seven years of exile, returned to his native land. It was not until 1819 that he was permitted to return to France, during the ministry of Marshal Gouvion Saint-Cyr. In 1831 Louis Philippe restored to him his title and rank in the Chamber of Peers.

Louis Napoleon raised him to the dignity of Marshal of France in the early part of 1849, and nominated him Chancellor of the Legion of Honour in August of the same year. On the 2d of December, 1851, Marshal Exelmans powerfully assisted in securing to the government of Napoleon the faithful adherence of the army. On the 3ist of July 1855, the Marshal was on his way to the house of the Princess Mathilde, in company with one of his sons, when he was suddenly jerked from his horse, and fell on the road, not far from the house, and died seven hours afterwards, and expired at two o'clock the next morning.

EXECUTION. [ATTACHMENT OF DEBT, S. 2; DETINER, S. 2; GOOZ, S. 2; EXEMPTION, S. 2; PANTRY, S. 2, EXHIBITION, S. 2.]

EXHIBITION OF 1851. The great Industrial Exhibition of 1851 was in itself an event of so much importance, one which excited such very general interest, and has been the parent of so many other exhibitions of a somewhat similar kind in different countries, that without entering upon the larger question of its initiatory or immediate influence upon manufacturing art and skill, or commercial enterprise—it may be useful to present in this work a brief summary of facts and figures illustrative of the history of the undertaking.

There had been industrial exhibitions in England and on the Continent, but they had been of a more or less local character, or at the utmost confined to the manufacturers of the country in which they took place. In England there had been the exhibition of 1816 held in the Haymarket, and another at the Royal Academy in 1826. This was in 1826 that the first real attempt was made to give the manufacturing art an impetus by a national exposition. Prince Albert was president. On its first announcement the project was coldly received, and some three years were suffered to elapse before it was again brought distinctly before the public. Meantime the annual exhibitions of the manufacturers were continued, and the feather trades and commercial men began to feel increased interest in the proposal. By the beginning of 1849 the council of the society had matured a plan, which in March of that year was submitted to the House of Commons, and was presented as an application for public aid. It was in the nature of a request for a parliamentary grant for pecuniary aid. Prince Albert, who had all along warmly supported the proposal, conceived that the time had arrived for imparting to it a much more magnificent form, by throwing the exhibition open to the industry of the
world. The council adopted his suggestion, and measures were taken for enlisting in behalf of the scheme the sympathy of the city in its promulgation, and then those of every other nation. The idea of an International Exhibition of Industry at once seized the general mind. At the preliminary meeting held in the city under the presidency of the Lord Mayor, for the purpose of enunciating the scheme, it was received with the utmost favor, and the provinces speedily gave in their cordial adhesion. The Council of the Society of Arts, which in the first instance assumed the direction of the undertaking, entered into contract with Mr. E. M. Wyon, as well as with Mr. W. M. Owen, for the purpose of publishing a prospectus and promoting the scheme. Upon the 1st of January 1851. a Building Committee, to whom was entrusted the entire arrangement of the Exhibition, was appointed. The great meeting was held at the Mansion House, at which the anxious desideration of various influential merchants and manufacturers was announced, and a general subscription was inaugurated with a view to raising funds for meeting eventual expenses. This large subscription was followed by corresponding meetings in every part of the country, and it was soon made evident that ample funds would be forthcoming. In fact a total of very nearly 80,000L. was ultimately reported to the Commissioners as subscribed, though only 87,000L. was paid into their bankers—upwards of 11,000L. having been somehow absorbed in the several localities as expenses. On the 21st of February, the Commissioners were able to make a public announcement of the general plan of the Exhibition, and to communicate the royal permission to hold it in Hyde Park.

The site granted for the building was on the south side of Hyde Park, between Kensington Drive and Rotten Row. The Commissioners announced that the building would cover an area of eleven acres, and that the transept and base of the great central building was the reception of goods by the 1st of January, 1851; that from that day to the 1st of March following goods would be received, and that the Exhibition would be open to the public on the 1st of May, 1851. In March 1850 the Building Committee appealed to architects and engineers to assist them with sketches and suggestions as to the form and general arrangements of the building required for the Exhibition. This appeal was responded to by a large number of professional men, including several foreign architects. In the course of May the Commissioners announced that they had examined the 243 designs sent in, but though several were of sufficient excellence to obtain special commendations, they were unable to select any one design which fulfilled all the conditions prescribed by the nature of the undertaking. Out of the 358 designs, however, singled out by the Commissioners for special commendation, and it was noticed as a curious circumstance that, though only 35 of the competing architects were foreigners, of the 18 of them specially distinguished only three were Englishmen. The Committee, being unable to recommend any one of the designs for adoption, the Commissioners stated that they had derived much valuable suggestion from the plans to guide them in preparing a design. After much deliberation by the Commissioners, a building was proposed which was to be 2000 feet long, 400 feet across, and to cover upwards of 20 acres. It was to be constructed of brick and lighted by skylights. The great feature of the building was to be a grand central hall, in shape a polygon of 16 sides, the main walls, which were to be of brick, being carried up to a height of 60 feet, and it was to be covered with an iron domical roof, much larger than any hitherto constructed, being 800 feet in length, and 300 feet in breadth, and running from St. Paul's, and 48 feet larger than that of the Pantheon of Rome. The report of the Building Committee gave general dissatisfaction in various ways, but their design—so obviously the result of a system of disinterested and forth a storm of diabolical disapprobation. For awhile the whole scheme seemed in peril, when Mr. (now Sir Joseph) Paxton came to the rescue by proposing an entirely new plan, that of a vast building of iron and glass resembling in its general principles the great conservatory at Chatsworth. This plan was at once adopted by the Commissioners, and put into execution at Chatsworth. Having powerful influence, he was enabled—though at this late hour when tenders had been publicly invited for the committee's design—to obtain permission to build his design before the Commissioners and his president. Its singularity and novelty were thought quite sufficient to meet the criticism, as well as the great comparative facility with which it could be erected and removed, at once commanded their approval. With the general public it from the first became popular, and as soon as the contractors, Messrs. Fox and Henderson, undertook its erection upon terms which removed all doubt of its economy as well as practicability, the Commissioners determined upon adopting it, and accepted Messrs. Fox and Henderson's tender. They were to receive 79,300L., the materials to be furnished at their own cost.

From this time all proceeded rapidly and smoothly. The contract was signed on the 26th of July; on the 80th the contractors obtained possession of the site; on the 26th of September the first column of the building was erected, and on the 19th of the 4th of October the foundations were laid. The contract was completed by the 31st of December the building was sufficiently advanced to allow of a lecture being delivered within it to the members of the Society of Arts, and on the 3rd of February, 1851, the completion being formally handed over to the Executive Committee.

The form and character of the building are too well known to need any detailed description. It will be enough to say, that its entire length was 1851 feet—its breadth, 405 feet, and its height, as far as the main roof, 80 feet. The upper story was 26 feet long by 48 wide. The central portion was 120 feet wide by 64 high; on either side of this was another portion 73 feet wide by 44 high; and the north and south portions were 72 feet wide by 24 high. The portions or great avenues here described ran east and west through the building: very near the centre the transept crossed, with a width of 75 feet and a height of 103. The entire area was 772,784 square feet, or about 19 acres—nearly seven times as much as St. Paul's Cathedral. The entire ground area was divided off into a central nave, four side aisles, and several exhibiters' courts and avenues. There were 3 entrances, with 8 pay places to each, and 18 doors for exit. Four galleries ran lengthwise along the sides of the building, and others around the transept, with direct access to the central nave, and double staircases. The iron columns in the building, with, which their connecting pieces, were about 20 and 24 feet high respectively, were about 3300 in number; and there were 1074 beam pieces beneath the columns, on which the whole structure rested. There were nearly 3000 girders, of three different lengths, 24, 48, and 72 feet, and of five different weights, 12, 15, 35, 120, and 160 cwt. Altogether there were about 4000 tons of iron built into the structure.

In the woodwork for the glass roof, the Paxton gutters were arranged 8 feet apart, with a ridge between every two. The squares of glass were 49 inches by 10. Besides the 17 acres of glass for the roof (none being wanted for the open air) there were about 1300 vertical glass ashes. The ground floor and the galleries contained 1,000,000 square feet of flooring. Of sash bars there were 200 miles, and 20 miles of Paxton gutters. The total woodwork in the building was estimated at 860,000 cubic feet. The form of the dwarf columns was specified, and the design of the cast iron that of the sash-bars, so likewise was the size of the panes of glass. The structure itself was built up of a series of bays or cubic compartments, each 24 feet square; each one being built up of, two, three, or four bays, so as to give the imported girders very ingeniously put together. Thus the entire ground-plan may be regarded as a series of these squares, the parallelogram being 77 of them in length and 17 in width—columns being of course omitted and longer girders substituted to form the nave, courts, and transept. The additional portion on the north side of the building was
The entire number of visitors was about 16,000.

The Exhibition was formally opened by her Majesty, on the 1st of May, 1851; it remained open 144 days, being smaller than the committee had calculated, and the arrangements were made accordingly. The Visites paid to the Exhibition was 6,063,986, being a daily average of 43,111. This average was not reached till June, but from that time till the close of the Exhibition there was comparatively little variation till the last week when the average was about 50,000. The number of visitors during this week was so extraordinary that we are tempted to set down the figures in detail.

Monday, October 6th, 107,316; Tuesday, 109,915; Wednesday, 109,760; Thursday, 90,613; Friday, 64,913; Saturday, 53,061. The following are three pairs of column of numbers:

1st number of visitors to the Exhibition was: Tuesday, 109,915; Wednesday, 109,760; Thursday, 90,613; Friday, 64,913; Saturday, 53,061; Sunday, 61,666. The six million visits paid to the Exhibition plainly indicate but very roughly the actual number of visitors. Some persons went doubtless ten or even twenty times during the season, a very large proportion went twice. After weighing the statistics of all kind of attendance, it is evident at the conclusion of the probable average of visits would be about three, and that consequently about two millions of persons visited the Exhibition.

An attempt was made to arrive at the number of foreign visitors by an examination of the number of persons whose passports were furnished by the French, German, Italian, and other governments, as well as by the Home Office, for all steam plyers passing the ports of England and the continent of Europe, and of returns furnished by the United States Legislation, from which it appeared that the total number of all who arrived from all parts of the world, between the 1st of April and the 30th of September, 1851, was 35,037; a number very far below what the common imagination had supposed. During the same period in 1850 the number of aliens who landed in England was 15,616, so that the government was obviously in error in supposing that they could not have visited this country for the express purpose of seeing the Exhibition, though probably a few of the remainder left these shores without visiting it. The largest number of visitors was from France, 9,477; then came Germany, 10,400, the United States, 6,000, Belgium, 3,700, Holland, 2,900. But if the numbers be considered in relation to the population of the several countries, it will be seen that Holland sent most visitors, Belgium next, then France, Germany, and the United States. The respective proportions of town and country visitors was attempted to be arrived at by comparing the arrivals in London, from April to October, by steam-boats and railways—of course a very rude method, but the only available one,—when it appeared that the arrivals in London were 2,161,647, from steam-boats and railways, of a number of 1,445,487. But as against this there had to be set off the regular yearly increase in the number of travellers by railway, and other allowances to be made; the inference was drawn that the number of persons who came from the provinces, to view the Exhibition slightly exceeded a million; roughly, we may say that the Exhibition was visited by about a million of the inhabitants of London, the same number from the provinces, and about 50,000 foreigners.

The details of the jury awards do not come within our present object; but the following are the general results, as affording materials for comparison.

There were 186 * Council Medals," 2976 "Prize Medals," and 204 "Honourable Mention," making a total of 5948 through all departments of the Exhibition. All kinds of numbers, up to the estimated number of 16,000, about one-thousand were deemed worthy of some kind of recognition. Of the total number, 2039 were taken by exhibitors belonging to the United Kingdom, 3080 by foreign exhibitors, 123 of whose names were derived while of the remainder 1600 came from the United Kingdom, and about 1070 from the Belgian colonies.
took off three-fifths of the honours. The greatly-coveted 'Council Medals' were awarded in the ratio of 79 to British and 87 to foreign exhibitors; the 'Prize Medals,' 1244 British and 1632 foreign; the 'Honourable Mentions,' 716 British and 1396 foreign.

In relation to different classes of exhibited articles, there were a few striking and instructive facts. In machinery, in manufactures, in metal, and in glass and porcelain manufactures, the prices of tells combined, was the ratio of three-fifths to two-fifths British. But in the section of raw materials for food and manufactures, the competiton was less keen; they were as many as prizes as the British (908 to 265). It would be a hasty generalisation to infer from thence that Britain is a manufacturing and not a producing country; but the simple facts themselves are worthy of note, whether we theorists concerning them or not.

The great honours, the Council Medals, were very unequally distributed as regards the classes of exhibited articles; for out of the whole number of 168, no less than 88 (more than one-half) were awarded for machinery alone. This is a significant fact; showing that the Juries, or rather the Council of Chairmen, were not deterred by the gorgeous display around them from doing justice to the great working agencies by which modern wealth is produced. What would be charged on the head of financial results. The receipts at, and in relation to, the Exhibition, by which it was made a self-supporting concern, were truly remarkable. The admissions were by season tickets, and by payment at the doors of season tickets. The receipts were 10,829, 10,829 men's tickets at three guineas each, and 5615 ladies' tickets at two guineas each, were sold before the Exhibition commenced, making together 19,607, for which more than 63,000L. were paid. About 6000 more tickets were sold during the Exhibition; the interest felt by the ladies in leaving the Exhibition, and it is worthy of note that of these 6000, the ladies took off nearly a thousand more than the gentlemen. The smallest money receipt at the doors was on the second day after the opening: the largest was on the third day before the closing; these sums were 32,685L. and 32,685L. respectively, the former in sovereigns and the latter in shillings. The average of the daily receipts at the doors was 2323L. There were two admission days at 1L., twenty-eight at 6L., thirty at 2L. 6L., twenty-eight at 2L. 6L., and 6500 for season-tickets only, two for exhibitors and their friends, and one for exhibitors and the officials; making up the total of a hundred and forty-four. The total receipts amounted in round numbers to 506,000L., that amount being thus made up: subscriptions 97,600L., entrance tickets to the Exhibition 232,685L., catalogue contracts, royalty on medals, washing-rooms, &c. 13,200L. The total expenditure connected with the Exhibition was about 330,000L., leaving a surplus of 176,000L. in the hands of the Commissioners, but the final balance, including the Commissioners' expenses, was 25,000L., and the receipts were 186,436L. How to apply this large surplus was a most important question. The original announcement to the subscribers was to the effect that, should any surplus remain, it was the intention of the Commissioners "to apply the same to purposes strictly in connection with the ends of the Exhibition, or for the establishment of similar exhibitions for the future." This latter purpose they were however led on more mature reflection to abandon, and they arrived at the scheme of distributing part of the surplus proceeds of a temporary, partial, or local character, they could in no way so properly act in the spirit of the pledges held out to the public as by assisting in carrying out a comprehensive scheme which should have for its object "to increase the means of industrial education and exert the talent, skill, science and art upon productive industry": they having been compelled by their experience, in connection with the Exhibition, to regard as a matter of urgent importance the "systematically inducing a feeling of respect for, and a spirit of advancement of, the class of the community, to enable them to maintain their pre-eminence in the markets of the world." In their Second Report (1852) the Commissioners review the existing means and deficiencies of the country in respect to these matters, and come to the conclusion that they "...merit the serious consideration of those who have to meet the requirements of the public and the Government. The sum in the hands of the Commissioners would go but a small way towards meeting the requirements of the case. It would suffice however to prepare the ground, and they determined so to employ it, leaving it to the public to complete the work when its importance and necessity shall have become fully understood. They felt sure that they could..."
their various branches, and to "establish a central point of
union for those who in so many ways devote their
energies to the same ends, especially in respect of the practical
application of science and art to productive industry." They
thus, in connection with the enlarged system of industrial
instruction of which they urged the necessity, hoped that
instead of being behind most other European nations we
might take the lead in industrial science and art, as well as in
the fostering of industry and enterprise. But the Com-
missioners have been deemed to see their scheme, like so
many another castle in oldland, reduced to much humbler
dimensions than that in which it at first presented itself to
their imagination. As a first step it was proposed to remove
the National Institution to a position nearer the centre,
and from there to build a thousand feet (the depth being practically
unlimited) nearly facing the site of the Exhibition of 1851, was proffered
by the Commissioners. A Committee of the House of Commons
in 1850 reported unanimously in its favour, and the Govern-
ment appeared to be inclined to support the proposition, but
the Commissioners appointed to consider the subject in 1857
decided by a majority of three votes to one against removing
the national collection from Traflagar Square; and in conse-
quence of their report a survey has been made of the ground in
the area, and estimates given of the cost of enlarging the present
building, or erecting a new one on its site. So with reference
to the Art-Collections in the British Museum, the feeling of the
Trustees has been decidedly expressed against any move-
ment. So again, a new building has been erected for the
collection of vegetable products at Kew, which were pro-
posed to be taken to Kensington. Then the Learned Societies were averse to moving so far westward, and
providing a new seat for their accommodation. Some of the
Rother

This is a very wide circulation. One of the

principles for the interpretation of prophecy which he highly
laboured to establish and explain, was, that the delin-
quencies of events in prophecy are not applicable to the destinies
of individuals, but to those of governments and nations. His
writings are numerous, and we can only mention a few of the
most important:— 1. Home Mosaics, or a View of the
Masonic Records, with respect to their Coincidence with
Prophetic Antiquity, their internal Credibility, and their Con-
nection with Christianity, 2 vols. 8vo, 1801; 2. A Dissertation
on the Mysteries of the Cabyl, or the great god of Phœnicia,
Samothrace, Egypt, Troas, Greece, Italy, and Crete, 2 vols.
8vo; 3. Dissertation on the Prophecies that have been fulfilled,
are now fulfilling, or will hereafter be fulfilled, relative to
the great Period of 1290 Years, 2 vols. 8vo, 1808; 4. A General and Connected View of the Prophecies relating to
the Conversion, Restoration, Union, and future Glory of
Judah and Israel, 2 vols. 8vo, 1808; 5. The Origin of Pagan
Idolatry, 3 vols. 8vo, 1816; 6. A Treatise on the Genius and
Object of the Patriarchal, the Levitical, and the Christian
Dispensation, 2 vols. 8vo, 1823; 7. The Sacred Calendar of
Prophecy, or a Dissertation on the Prophecies which relate to
the Grand Period of Seven Times, 3 vols. 8vo, 1828; 8. Eight Dissertations on certain connected Propohetical Pas-
sages of Holy Scriptures bearing more or less upon the
Prophecies; 9. The Deliverer, 2 vols. 8vo, 1845.

FAR

FABER, REV. GEORGE STANLEY, was born on the
25th of October 1773. He was the eldest son of the Rev.
Thomas Faber, who was descended from a French refugee
who came over to England after the revocation of the edict
of Nantes. He was educated at the grammar-school of
Heppenheim, near Halifaks in Yorkshire, where he remained
until 1790, when he entered University College, Oxford.
He took his degree of B.A. in 1792, and before he had
reached his twenty-first year, was elected a Fellow and
Tutor of Lincoln College. He took his degree of M.A. in
1796, served the office of Proctor in 1801, and in the same
year, as Bampton Lecturer, preached the discourses which he
shortly afterwards published under the title of "Home
Mosaics." He took the degree of B.D. in 1803, and married
in the same year. Having by this step relinquished his
fellowship, he went to reside with his father at Calverley,
near Bradford in Yorkshire, where for two years he acted as
curate. In 1805 he was collated to the vicarage of Stockton-
upon-Tees, in the county of Durham, which he resigned in
1811, and was appointed a small, in the same county. In
1811 he was collated to the vicarage of Long-Newton, where
he remained till 1831, when Bishop Burgess presented him to
a prebend in the cathedral of Salisbury. In 1832 Bishop
Van Mildert gave him the mastership of Sherburn Hospital,
making him also vicar of the parish, when it became a vicarage
of Long-Newton. During his mastership he considerably
increased the value of the estates of the Hospital. He rebuilt
the chapel, the house, and the offices, and greatly improved
the grounds; he augmented the incomes of the incumbents
of livings near him, by giving them large rents of the estates
of their churches, and erected agricultural buildings on the farms.
He died at his residence, Sherburn Hospital, on the 27th of
January, 1854.

1850 Theological writings of Mr. Faber, particularly those
on prophecy, had a very wide circulation. One of the

the promotion of Industrial Art and Science; and to which
was intrusted the direction of all previously existing govern-
ment scientific and art institutions, and the encouragement
of all local institutions of a similar order. [Sources and Art.
DEPARTMENT OF, S. 3.] Upon the estate purchased by
the Commissioners a great practical step towards the realisation
of a main feature of their scheme has been taken. In
a building which has been adapted to the purpose, instruction
in practical science and art, and meetings of the highest
standing is regularly given, and an excellent library
has been formed for the use of the students; more strictly
scientific courses of lectures are at the same time delivered
at the Metropolitan School of Science, in Jermyn Street—
though the Commissioners have not yet united a school nearly
residential that resembling that desired by the Commissioners. In
a spacious temporary iron building at the south-eastern
angle of the estate have been brought together for public
exhibition industrial, educational, and art collections, which,
though as yet necessarily very incomplete, and in some
parts only rudimentary, are all of great value and interest;
and having been arranged and shown so as to suit the
convenience of the industrial classes, they have proved
remarkably attractive. These collections include a Museum
of Patent Inventions, a Trade Museum, a Museum of Ancient
and Modern Manufactures, a Museum of Animal Products,
and a Museum of Domestic Economy, the Architectural Museum
formerly exhibited in Cannon Row, the fine collection of
paintings and engravings at Oxford, the museum of Mr. Shee.
shanks, and collections of British sculp-
tures, drawings, etchings, &c. At the present moment [March
1850], a collection of models and drawings submitted in
competition for the Memorial, to be erected in commemora-
tion of the Great Exhibition is also being exhibited in the
'south Kensington Museum,' but the true memorial of
the Exhibition of 1851 will be the Exhibition Estate, with the
Museums of Art and Industrial Science collected upon it.

EXILE. [See Sav厌恶 Patents, &c.] EXOCUS. [Fighting Pests.
EYEBRIGHT. [Euphrasia.]
1811) work which had some reputation, and contributed to the 'Agricultural Magazine.' Farey, junior— with his brothers and sisters, becoming at an early age attached to kindred pursuits— was engaged in making drawings for the plates of 'Rosa's Encyclopaedia,' 'The Edinburgh Encyclopaedia,' 'Tilloch's Magazine,' 'Gregory's Mechanics,' and 'Mechanical Dictionary,' the 'Antiquary,' and many other publications, of some of which he contributed articles and sketches. To have been the inventor of these Lowry, the engravers, has been ascribed in a great degree, the merit of introducing a better explanatory style of illustration in scientific works, and which has not since been improved upon in this country, or in France. Races of Kindred, and mechanical facilities. His acquaintance connected him with eminent scientific men of the time; and thus with Huddart, Josep, Myine, and Bennie, he was engaged in the publication of Smollett's reports and drawings. In 1807 he had received the silver medal of the Society of Arts for an instrument for making perspective drawings, described in their 'Transactions,' and in 1813 the gold medal was awarded to him on the invention of his machine for drawing ellipses. This last he afterwards improved upon, besides making many improvements in the scales and drawing instruments now in use. In 1819 he went to Russia, and was engaged in the construction of iron-works. In Russia he first saw a steam-engine indicator—an instrument which it was attempted to apply to a great extent in England; but was then only manufactured, and was often employed to use them in disputed cases. In 1831 he resigned his professional engagements in favour of his brother, and embarked in a lace manufactory in Devonshire, but gave that up in 1833. In 1830 he took the engineer's degree at the Ecole Polytechnique, and in 1831, on the failure of his brother's health, he returned to London, and from that time to near his death, which took place in his sixty-first year, on the 17th of July 1831, he was employed as a consulting engineer, or referee, in most of the novel inventions and litigation connected with steam, during the quarter of a century. For such duties he was peculiarly qualified from retentive memory as to details of machines and processes, names and dates, and from habits of conscientious and laboured attentiveness. He is said to have been reticent, and in the preparation of drawings for specifications, he was assisted by his wife, a lady of great scientific attainments. From the shock of her decease he never wholly recovered. Some time before, part of his library and documents had been burnt with his house in Guildford-street. Farey commenced a 'Treatise on the Steam-engine, Historical, Practical, and Descriptive,' (4to, London, 1827, with plates,) a valuable work, but which did not get beyond a first volume, and he was an active member of the Institution of Civil Engineers, from whose Report of 1851-62 many of these particulars are derived.

FARINGDON. [Farringdon.] F. A. T. (Tiers, Organo, S. J.)

FARRINGTON, G. P. F., one of the most prominent members of the French government, and a writer on subjects of political economy and social progress, was occupied during the greater part of his life as a journalist. His connection with the periodical press of Paris commenced about the year 1839; from 1836 to 1843 he was a contributor to the 'Courrier Français,' and was afterwards a leading writer in the 'Revue des Deux Mondes,' which is published on the 1st and 15th of every month, and occupies an influential place among those periodicals which are chiefly devoted to the discussion of questions of country, and the investigation of the actual condition of the various nations of the world. M. Léon Faucher was, during the last ten years of the dynasty of Louis Philippe, a member of the Chamber of Deputies for the department of Marna. He was re-elected by the same department in 1848 as one of its representatives in the National Assembly of the French Republic. He became Minister of the Interior, December 29, 1848, and held the office till May 14, 1849. He was again appointed Minister of the Interior February 3, 1853, and served in that capacity till January 29, 1855. M. Léon Faucher died on the 15th of December 1854, at Marseille.

M. Léon Faucher published in 1845 'Études sur l'Angleterre,' 2 vols. 8vo, Paris, a work of great weight, in which he treated of the districts of England—White-chapel, St. Giles's, the City; Liverpool, Manchester, Leeds, Birmingham, and adjoining districts—together with dissertations on the Bank of England, the Lower Classes, Middle Classes, Aristocracy, the Corn-Laws and the League, and the Balance of Powers. Several portions of this work appeared in 1845 and 1846 in the 'Revue des Deux Mondes,' and the description of Manchester had been translated into English under the title of Manchester in 1844; 'Represent Condition,' 12mo. The work is written in a fair and impartial spirit, and affords evidence of diligent research and patient investigation; but contains many mistaken views and exaggerated descriptions. Other dissertations by M. Léon Faucher, under the title where: —De l'Impôt, under the title: —Du Système de M. Louis Blanc. —De la Sitaition Financière et du Budget, 8vo, 1850, appeared originally in the 'Revue des Deux Mondes,' in 1849. He was a member of the Board of the Demonstration of Gold in several Countries, in Europe, by Mons. Léon Faucher; translated by Thomas Hanley, Junior, 8vo, Lond., 1853. These remarks appeared first in the 'Revue des Deux Mondes,' and were subsequently published, somewhat modified, in the Reports of the Académie des Sciences Morales et Politiques.

FAUJASITE. [Mineralogy, S. J.] FERRIERE, MISS, was born at Edinburgh, about 1752, the daughter of a writer to the signet, and was one of Sir W. Scott's colleagues as clerk of the Court of Session. This association almost necessarily produced an intimacy with the Scott family, and she had early access to the company of the best literary society of her native city. She was received into the society when Miss Scott, his first and only wife, died, and was introduced as an agreeable character, by "the very lively work entitled 'Marriage.'" In the latter part of his life, when Miss Ferriere was one of his most trusted friends, her name occurs in his diary. Her novels are not entirely national; the characters are vigorously drawn, and the love of either fame or profit. Sir Walter Scott, indeed, says of her, that in conversation "she was the least exiguate of any author, female at least, whom I have ever seen." He adds: "she was a simple, full, and exact expositor of herREADY READER upon the grosser errors of human conduct; the sketches are relieved by scenes of harmony, which, if sometimes exaggerated, like those of Miss Burney, are certainly laughable.

Miss Ferriere passed a peaceful and quiet life in her native town, associated with all the more distinguished of her contemporaries, and respected for her kindness and urbanity by every one who knew her. She died, aged seventy-two, in November 1826. FEVEREWS. [Feverwms, S. J.] FIBROUS TISSUE. [Tiers, Organo, S. J.] FICHETELITE. [Chemistry, S. J.] FIELDSFARE. [Furniture.] FILDING, COPELY W. ATKINSON, was born about 1787, and belonged to a family several of the members of which were artists of greater or less ability. Copley Fielding exhibited his first pictures at the Artists' Exhibition, Spring Gardens, in 1810. It was by his water-colour landscapes that he first made people familiar with his name. He had made many attempts to achieve success as a painter in oil, in his paintings in water-colours that he will be remembered. Mr. Fielding began the practice of the art about the same time that Copley was successful. He succeeded in raising the practice of water-colour painting almost to the same extent of oil-colours, and Fielding devoted himself with thorough earnestness of purpose to the new art. From an early period in his career he became a teacher, and he had in that line an unequal measure of success, as
well in the progress of his pupils as in their number and social position. His success as a teacher of course did much to swell the ranks of his friends, and of course to raise the merits of his works effectually maintained. His course was one of steady prosperity, quite devoid of adventure. His time, was constantly occupied either in teaching or painting, or in those sketching excursions which were to furnish him with materials for his new picture. Mr. Fielding held the office of President of the Society of Painters in Water-Colours, and his position was generally recognized as that of the head and representative of this branch; he was, more kindly, no doubt, the object of the estimation in which his personal as well as professional qualities were universally held. He died March 3, 1856, in his sixty-eighth year, at Worthing, Sussex, where, or at Brighton, he had for a long period been accustomed to reside.

FIGITES. [GALLO DICHA]

FILICIES, or FILICA/CEA, a natural order of Plants, being the highest group of the class Cryptogamaceae, or Acro- gena. The species are few. These plants, consisting of leafy fronds, which are produced from a rhizome unfolding in a spiral manner, and traversed by veins which form definite parts on the under surface, and produce unilocular, rarely multilocular, cases containing reproductive spores.

These plants, which are so well known and of such importance in their study, and on modifications of which modern classifications depend, are the veins and organs of reproduction. The veins are either produced equally from both sides of a midrib, or they radiate from the base or axis of development, or from the extremity of the stem; these parts are either simple, or once or repeatedly dichotomously branched, or the primary veins are pinnate; the branches are simple or forked. Their apices are either free, or they are combined by various forms of anastomosis. The organs of reproduction consist of a sporangiferous receptacle, which is a thickened point or lengthened portion of the ultimate venales or veins. It is generally superficial, sometimes immersed in the substance of the frond, or considerably elevated, and is surrounded by various forms of anastomosis. The organs of reproduction are covered by the surface, or the surface, or the capsule, or the spore, or cases, are transparent, globose, oval, or pyriform unilocular cases, each girded by a more or less complete elastic articulated ring, or destitute of a ring; or sometimes closed, opaque, and multilocular, and usually pedicellate. The spores are collections of sporangia, and have the same form, position, and direction as the receptacles.

They are either naked, or each sorus is furnished with a membranaceous covering of various forms which raises from the receptacle. The sorus is covered or covered by a plane, or vaulted, or cup-shaped membrane, produced from the receptacle of each sorus, and is generally deciduous as it becomes reproductive. Often the entire margin (or lobules of the capsule) is of characteristic texture, and forms an accessory indusium. Sometimes the whole of each receptacle is included within a universal indusium which is formed by the revolute margin of fertile contracted fronds.

The following account of the reproduction of the Ferns is given in a Report to the British Association in 1851, on the higher Cryptogamous Plants, by Mr. Henfrey. Speaking of the Ferns, Mr. Henfrey says:—

This class formed for a long time the great stumbling-block to those who sought to demonstrate the existence of sexuality in plants. The young capsules were generally considered as the analogues of the pistillids of the Moosae, and the young abortive capsules which frequently occur among the fertile ones were supposed by some authors to represent a sex. Mr. Griffith noticed a structure which he was inclined to regard as the analogues of the antheridium in certain of the ramentae upon the petioles.

In the year 1844 Professor Nageli published an account of his observations on the germination of certain fronds, and announced the discovery of moving spiral frond stems closely resembling those of the Chares; on certain cellular structures developed upon the pro-embryo or cellular body first produced by the sperm. It is not worth while to enter into an account of these discoveries, as they have since been clearly shown to have been very imperfectly understood, and to understand that he only described one kind of organ, and from his description it is evident that he confounded the two kinds actually discovered, regarding them as different stages of one structure. The result of these observations was to destroy all grounds for the assumption of distinct sexes, not only in Ferns, but in the other Cryptogams, since it was argued that the existence of these cellular organs, producing spiral frond stems, the so-called spermatozoon, upon the germ-cells of the plants, is an assumption which is untenable as in any way connected with the reproductive processes.

But an essay published by the Count Suminski in 1848 totally changed the face of the question, and opened a wide field for speculation and investigation into the subject, just as the discovery of the sperm had fallen into disfavor. Count Suminski’s paper gives a minute history of the course of development of the Fern, from the germination of the spore to the production of the regular fronds; and he found this development to exhibit a highly characteristic structure in each of the cellular organs of two distinct kinds. The first, which he terms antheridia, are the more numerous, and consist of somewhat globular cells seated on and arising from single cells of the cellular Marchantia-like frond. The globular cell produces a single frond in each of which is developed a spiral frond, coiled up in the interior. At a certain epoch the globular cell bursts, and discharges the vesicles, and the spiral frond movements within the vesicles, and length make their way out through the base, and swim about in the water, displaying a spiral or helical form, and consisting of a delicate filament with a thickened clavate extremity; this, the so-called head, being said by Count Suminski to be a hollow vesicle, and to be furnished with a spiral filament within the vesicle. The spontaneous and voluntary movement of the filament is supposed to be effected.

The second kind of organ, the so-called ‘ovules,’ are fewer in number and present different character in different stages. At first they appear as little round cavities in the cellular fronds of the pro-embryo, lying near the center, and opening on the under side. In the bottom of the cavity is seen a little globular cell, the so-called ‘embryo-sac.’ It is stated by Count Suminski, that while the ovule is in this state one of the globular cells in each of the cavities comes in contact with the central globular cell. The four cells bounding the mouth of the orifice grow out from the general surface into a blunt cone-like process, formed of four parallel cells arranged in a squarish form, and leaving an indentation on the surface. From each indusium each of the four cells become divided by cross septa, and grow out until the so-called ovule exhibits internally a cylindrical form composed of four tiers of cells, the uppermost of which gradually converges and closes, leaving at the tip of the stem a swelling down between them. Meanwhile the vesicular head of one of the spiral frond stems has penetrated into the globular cells of the embryo-sac, enlarged in size and undergone multiplication, and in the course of time displays itself as the embryo, producing the first frond and the terminal bud, whence the regular fern-stem is developed. In considering the import of these phenomena, the author assumes the analogy here to be with the process of fertilization in flowering plants, as described by Schleiden, regarding the production of the embryo from the vesicular head of the spermatozoon, as representing the production of the phanerogamous embryo, from the end of the pollen tube after it has penetrated into the embryo-sac.

The preceding statement naturally attracted great attention, and since they appeared we have received several contributions to the history of these remarkable structures, some confirmatory, to a certain degree, of Sumin- ski’s views; others altogether opposed to them. Mr. Griffith published a series of researches on this subject, in which he subjected the assertions of Suminski to a strict practical criticism; the conclusions he arrived at were altogether opposed to that of the author, and he never observed the entrance of the spiral frond stems into the cavity of the so-called ovule. About the
same time M. Thuret published a series of observations on the 'Antheridia of Ferns.' In these he merely confirmed and correlated the spiral filaments respecting the antheridia, and did not notice the so-called ovules.

Towards the close of the same year Hofmeister confirmed part of Suminiski's statements, and opposed others. He stated that he had observed daily the production of the young plant (or rather the terminations of the young) in the interior of the so-called ovule; but believed the supposed origin of it from the end of the spiral filament to be a delusion. He regards the globular cell at the base of the canal of the ovule (this is the cell, or embryonal vesicle (the embryonic originating from a free cell produced in this), analogous to that produced in the pistillidia of the Mosses. He also describes the development of the ovule differently, saying that the canal and orifice are opened only at a late period, and the separation of the contiguous walls of the four rows of cells.

About the same time appeared an elaborate paper on the same subject by Dr. Hermann Schacht, whose results were also independent. He found the young terminal bud had developed in the cavity of one of the so-called ovules, which were developed exactly in the same way as the pistillidia of the Mosses. He stated also that the cavity of the ovule is not open at first, and he declares against the probability of the filament having been seen in it by others; he observed this, much less a conversion of one into an embryo.

In the essay of Dr. Mettenius, already referred to, an account of the development of the so-called ovules is given. His observations did not decide whether the canal of the ovule, which he supposed to be at first only a canal, was opened only subsequently, when it is entirely closed above. Some important points occur in reference to the contents of the canal. The contents of the canal in a mature condition consist of a continuous mass of homogenous tough substance, in which five granules, and here and there large corpuscles, are embedded. It reaches down to the globular cell, or embryo-sac, and is in contact with it. This mass either fills the canal or diminishes in diameter from the end of the canal down to the embryo-sac; in other cases it forms the cell represented by Suminiski, having a cavity enlargement at the blind end of the canal, and passing into a twisted filament below; in this latter shape it may frequently be pressed out of the isolated ovules under the microscope, and then a thin transparent membrane-like layer was several times observed in its surface. In other cases the contents consisted of unclotted vesicles, which separated or connected together.

"The embryo-sac consists of a globular cell containing a nucleus, and this author believes that the commencement of the embryo consists in the passage of the globular cell into this two, which go on dividing to produce the cellular structure of the first frond.

With regard to the contents of the canal the author says, 'Although the Filicidia of the Flora, to which I refer regard to the origin of the contents of the canal of the ovule, yet my observations on the development of the ovule do not allow me to consider them, with Suminiski, as spiral filaments in course of solution; just as little have I been able to convince myself of the existence of the process of impregnation described by that author. It rather appears to me that the possibility of the entrance of the spiral filaments and the impregnation cannot exist until the tearing open of the blind end of the canal in the perfectly-formed ovule, as after the opening of the so-called canal of the style in the pistillidia of the Mosses.

"Another contribution has been furnished by Dr. Mercklin, the original of which I have not seen, but depend on analyses of it published in the 'Botanische Zeitung,' and the Flora for 1851, and further in a letter from Dr. Mercklin to M. Schacht, which appeared in the 'Linnaea' at the close of last year.

He refers in a few subordinate particulars from M. Schacht, in reference to the development and structure of the prothallium, or pro-embryo, and of the antheridia and spiral filaments; but these do not require special mention, except in reference to the vesicular end of the spiral filaments, which is represented as having a residuum of the parent vesicle, from which the filament had not become quite freed. The observations referring to the so-called ovule, and the supposed process of impregnation, are very important; they are as follows:

1. The spiral filaments surround the ovule in numbers, frequently returning to one and the same organ.
2. They can penetrate into ovules. This was seen only three times in the course of a whole year, and under different circumstances. In a spiral filaments originating the antheridia, and did not notice the so-called ovules.
3. In the proximal part of the ovule, almost in every case, peculiar club-shaped granular mucilaginous filaments occur at a late period; these are a prolongation of the spiral filaments, acquiring a brown colour with iodine. These mucilaginous bodies sometimes exhibit a twisted aspect, an opaque nucleus, or a membranous layer, peculiarities which seem to indicate the existence of an organisation.
4. The spiral filaments are often at the lower capitate extremity, and have been found in contact with the embryo-sac, or globular cell, which forms the rudiment of the future frond.
5. The spiral filaments, which cease to move and fall upon the prothallium, are metamorphosed, become granular, and swell up.

"Hence the author deduces the following conclusions:

That these clavate filiform masses in the interior of the ovule are filaments, which, at an early period, whilst the ovule was open, have penetrated into it; which leads to the probability that—

1. The spiral filaments must regularly penetrate into the ovules; and, 2. They probably contribute to the origin of the developement of the frond upon the ovule, in what way this happens the author knows not, and the details on this point given by Suminiski remain unconfirmed facts.

An important point in this essay is the view the author takes of the whole process of development in this case. He regards it as not analogous to the impregnation in the Phanerogamia, since the essential fact is merely the development of a frond from one cell of the prothallium, which he considers to be merely one of the changes of the 1. It is the first stage, each

The position of the Ferns in a natural system of classification has not been a matter of much difference. Their imperfect organs of reproduction have at once led to their being placed by most botanists among Cryptogamia; nevertheless Bory St.-Vincent elevates Ferns to the rank of a class intermediate between Monocotyledons and Acotyledons, or Cryptogamia; at the same time he rejects the view of Jussieu, who, from the mode of germination of their spores, placed the Ferns among the Monocotyledons. Their relation with the flowering-plants is seen through Cystocaulus, with which order they agree in their gyrate formation and their pinnate leaves. Their affinity with Cryptogamia plants is obvious in the Equisetaceae and Lycopodiaceae.

The order of the Ferns may be divided into the following sub-orders, which Lindley regards as of the rank and value of orders:

1. ORCHIDEAE. The these with a transverse or obliquely transverse complete elastic annulus or ring, bursting vertically. The species are tropical, or extra-tropical only in the southern hemisphere, of a habit simple or variously compound, or generally with conspicuous dichotomous branches and gemmae in the axils; the ultimate branches pinnatifid. None of the genera of this order, as understood by Hooker, are British.
2. POLYGONAE. With the sori dorsal, often near or at the margin, various in form, sometimes constituting an uniform linear or spreading mass, naked or furnished with an involucrum, the these I-celled, with a longitudinal or oblique elastic articulated generally incomplete ring, bursting transversely and irregularly. This is a very extensive sub-order: the species
inhabit almost every part of the world, from the tropics to the arctic and antarctic regions; they are exceedingly variable in size and appearance, including the largest tree-ferns and the smallest herbaceous species. It contains by far the largest number of genera of any of the sub-orders of Pteridophyta. No two of them are alike in form, and have no British representatives, as Cyathæn, Henmiææ, Allophilia, Dicksonia, &c.

3. Osmundaceæ. The thecae have an ovoidicular form, or without one, recticulated, striaed with rays at the apex, bursting lengthwise, and usually externally. The species of this sub-order are not numerous.

IV. Dennlaceæ. The theca sessile, without any ring, concrete into multiocular sub-immersed masses, opening at the apex. This is also a small sub-order, with three genera — Deppea, Zephyropus.

V. Osmoideæ. The theca single, roundish, coriaceous, opaque, without trirgul or cellular reticulation, half 2-valved, with a straight vernation. It embraces the genera Ophioglossum, Hélonostachya, and Botrychium.

The following is an arrangement of the British genera of Ferns —

 Tribe Asplenieæ. The sorus oblong or linear, covered by an indusium opening longitudinally on one side. Genus, Athyrium, Asplenium, Scelopendrium.

 Tribe Osmundaceæ. The sorus elongate, without an indusium. Genus, Osmunda.

 Tribe Adiantarieæ. The theca covered by a marginal or sub-marginal elongated part of the frond, or by a separated portion of the uterus, resembling an indusium. Genus, Blechnum, Pteris, Adiantum.

 Tribe Hymenophyllieæ. The theca opening irregularly; the ring oblique, erect, transverse, complete; the receptacle terminating a vein at the margin of the frond. Genus, Trichomanes, Hymenophyllum.

Sub-Order Osmundaceæ. Tribe Osmundæ. The vernation cincture; the rachis solid. The theca stalked.

Tribe Osmunda. Genus, Osmunda.

Sub-Order Ophioglosseæ. Genus, Ophioglossen, Botrychium.

The Ferns have a wide geographical distribution, the heleophytes often being found towards the north and south poles; whilst the tree-ferns rival the gigantic palms in the forests of tropical climates. It is these last which give a peculiar character to the vegetation of the countries where they grow, as their foliage and stems differ altogether from any that they are able to flower plants. The proportion which they bear to other plants varies much in different parts of the world. In Jamaica they are in the proportion of 1 to 9; in New Guinea as 28 to 128; in New Zealand as 13 to 60; in the Sandwich Islands as 42 to 160; on continents they are less numerous; in equinoctial America 1 to 36; in Australia 1 to 37; in France 1 to 63; in Portugal 1 to 116; in the Greek Archipelago 1 to 257; in Egypt 1 to 971. In the north their parts are shared by them, as they do in Scotland 1 to 31; in Sweden 1 to 35; in Iceland 1 to 18; in Greenland 1 to 10; and the North Cape 1 to 7.

The properties and uses of the Ferns are not in proportion to their numbers in the vegetable kingdom. Many of them deposit starch in their rhizomata, from which food may be prepared. The roots of Nephrolepis exaltata are eaten in Nepal; those of Angiopteris evecta are used in the same manner in the Sandwich Islands. Diplazium exaltata, Cyathæn, Pteris evecta, and Gleichenia dichotoma, all yield starch, and are employed as food in different countries. The Adiantum Capillus Veneris yields astringent and aromatic secretions. Some of the American polypondiums are said to possess medicinal effects, and are used as anti-rheumatic, and purifying remedies. The Angiopteris evecta yields an aromatic oil, which is used in the Sandwich Islands to perfume the fixed oils, as cocacnut oil. The stems of many species contain bitter principles, and have hence been used as tonics. Species of Aspidium and Asplenium have been used in European medicine. The Brazilian negroes form tubes for their pipes from the stems of Mertensia dichotoma. Osmunda regalis had at one time a great reputation in medicine.

FILLANS, James, sculptor, was born at Wilsontown, Lanarkshire, on the 27th of March, 1808. His father having become reduced in circumstances, removed into Renfrewshire where James was yet a child, and the boy was early set to the drudgery of his art. The many advantages which he received from the good working-classes of Glasgow, which also, by the way, has been chiefly the source of the additional facilities that city afforded for improvement in art, as in the expectation of increased patronage. He however met with both, and after a time was in a condition to visit Paris for the purpose of further study. On his return, his success having received a commission for a bust of Mr. Oswald of Auchenincruite, for his tenantry, which led him to visit Italy. Mr. Oswald being then resident on the continent. While still depending upon portrait busts for his means of support, Mr. Fillans was notnegligent of other subjects. His chief work of this class is a life-group in marble, 'The Blind teaching the Blind,' a work of real merit and some originality; it was exhibited in Glasgow, where it produced a great sensation. His 'Boy and Fawn' was considered by many as the most successful production of his class, and his next in order of time established his fame as Sir James Shaw, for the baronet's native town of Kilmarnock, and the bust of John Wilson — both characteristic works, that of Wilson being indeed by far the most striking head of the poet. His classical studies had been received with enthusiasm, and the sculptor was congratulated with two or three public dinners given in his honor. Still, though so far successful, he found his income insufficient to maintain establishments in London and Glasgow, and he resolved to quit the metropolis, his commissions having been chiefly derived from his countrymen. He removed to Glasgow in 1851, but his health, already impaired, became gradually worse; and at length an attack of rheumatic fever caused his death on the 27th of November, 1854. He had long been engaged as long as his strength permitted upon a colossal statue of 'The Fisherwoman of Renfrew,' but left it unfinished.

A life of James Fillans, by James Paterson, was published at Paisley in 1854, in a handsome quarto volume. It contains engravings of his principal works, as well as his designs for Motherwell's tomb, the Burns' series, an elaborate series of designs of 'Tamming the Wild Horse,' and a set of designs illustrative of a tale by a friend. It also contains several illustrations of the city, rivers, and country of Renfrewshire, which would have been as well left in the manuscript, except as evidence of the sculptor's kindheartedness. Fillans used the pencil as well as the chisel, but with so mean equal success.

FINDEN, William, line engraver, was born in 1757. He was apprenticed to Mr. Milian, an engraver of shop-bills, coats of arms, &c., but by devoting his leisure to the study

FLO

of the works of James Heath, and others, he acquired, by his own industry and intelligence, so much facility in the use of the burin, and displayed so cultivated a taste, that after he began to work on his own account he soon found ample employment in engraving book-plates. Among his first successes in this line, his engravings of Smirke’s illustrations of ‘Don Quixote’ have been singled out for special commendation.

Being very industrious, and always remarkable for a certain coolness of line and smoothness of finish, he grew in course of time into a favorite with the publishers, and he was selected to engrave ‘the royal portrait’ by Lawrence, of George IV. seated on the sofa. It was a plate of large size, and for engraving it Mr. Finden received the sum of £150; a sum that was difficult to earn in those days, bestowed upon it the utmost care, and it was so extremely popular that proofs and prints are said to have been advertised for at a large advance of price. But both the picture and the engraving were in an essentially false style of art, and, the fashion having passed away, they have sunk in general estimation even below their proper level. Among Mr. Finden’s other more celebrated large engravings, may be mentioned the ‘Village Festival,’ from the well-known picture by Wilkie, now in the National Gallery, which, with something of the fire of his mind:—firstly, it is inferior to his engraving; and the ‘Highlander’s Return,’ also after Wilkie.

Still his greatest success had been in small plates, especially in book-plates, and the great request in which he was held gradually enabled him to place himself in the inferior hands for the completion of his many engagements. To such an extent did he carry this, that he had at length, in conjunction with a younger brother, Mr. Edward Finden, also a skilful engraver, established a complete manuscript for the printing of the small plates. The effect was, of course, mischievous to art; injurious to his own reputation, as necessarily tending to destroy individuality of style; and eventually it was ruinous to his fortune, by inducing him to undertake—partly no doubt to keep his establishment in full employment, and partly to give himself a share of the profits which he fancied belonged of right to the engraver rather than to the publisher—the publication of various extensive series of engravings. Of these, the first and most various was the popular ‘British Art’ (1808). Oh! for such and such amiable works, and sets of illustrative pictures, with less success; and ultimately by far the best of the whole ‘The Gallery of British Art’—a generally well selected, well-engraved, and characteristic series of engravings from our best painters—on a larger and more costly scale than any of his previous speculations, was undertaken at an unfortunate time, and, being persevered in, in hopes of eventually retrieving the losses, swept away the fruits of all his previous labour.

After this, Mr. Finden’s only important work was a large engraving of his brother’s design, the ‘Dying Dutchman.’ But it was the work of a man broken in spirit, and is a very unsatisfactory production. He completed it shortly before his death, which occurred on the 20th of September, 1843.

FLAGS. [Is. 1.] FLIXW. [Sib. Eran.] FLORIS, an island in the Indian Archipelago, lying between 8° and 9° s. lat., 130° and 132° E. long. Its length is about 200 miles from east to west, and its average breadth about 35 miles. The surface of the island is hilly, particularly on the south side, where there are several high volcanic mountains, from one of which there was an eruption in 1810. Cotton is one of the products. Sandal-wood, bees-wax, handsome ebony, and a hard wood, which has a peculiarity of odor, are also found. The port, Ende, is on the south side of the island; it has an excellent harbour. Laranuku, a town on the east side, on the straits of Laranuku, in 4° 49’ s. lat., 133° E. long., is in the possession of the Portuguese, who have succeeded in bringing many of the natives to the profession of the Roman Catholic faith. This is the only part of the island in possession of Europeans. Ende was formerly subordinate to the Dutch presidency at Coogong in the island of Timor; but in 1818 the Dutch transferred their authority to Ende. The coast is mostly colonised by Biquos and Malays, but the interior is inhabited by aborigines, a dark curvy-headed race, who resemble the Papuas of New Guinea. The island gives name to the genus Floris, which separates it from the islands of Solor and Adan on the east.

FLOWER, that part of a plant in which the organs of reproduction are placed. The flower originates from a bud, and is nothing more than a particular modification in the perfecting of the parts contained in the bud; namely, the several organ parts and internodes. Only two essential processes of development can exist, and from these only two essential organs, as fundamental organs, can be formed in the flower; namely, the stamens and the pistil. The several parts of the flower must therefore be referrible to these fundamental organs, and be traced back to them. Since Goethe’s time this tracing back has been termed the Metamorphosis of Plants. Originally this mode of considering the flower rested upon the observation of cases in which the interruption of the usual processes of development, in some or all parts of the flower, caused those parts to resume forms in which it was not the nature of the fundamental organ from which they had been produced. This latter has been termed Retrogressive Metamorphosis.

As examples of it, we may mention the different monstrosities, the doubling of a flower through the transition of the stamens into petals, the transition of the petals and sepalas into the common leaves of the plant, &c. This mode of establishing the foundations of the doctrine of metamorphosis has however two essential faults: since, in the first place, it seeks to obtain individual facts by means of hypotheses and comparisons; while, secondly, it is based upon accidental and unfavourable circumstances. The only correct and sure ground on which to rest this doctrine is the history of development.

In Phanerogamic Flowers the following parts are distinguished:—

1. The Folia, or the External Calyx (Epioalyx), of which the parts are Leaves (Phylla); the Calyx, the parts of which are Sepals; the Corolla, the separate portions of which are Petals; or, instead of these three, the Perianth (Periannelium), which consists of those separate parts.—

2. The Stamens (Stamiuns), around and within which some stunted accessory follicular organs appear under very various names: and lastly, 3. in the centre of the flower, the Pistil (Pistillum), the separate follicular organs of which are Carpels (Carpelia). In the flower the Sepals are the lower threesepaelti, which is an indeniable circumstance. The upper free part, which is usually covered with papilles, is termed the Stigma, and between these two frequently a stalk-like elongation of the germin occurs, called the Style.

The flower of Phanerogamia is the only physiologically determinate organ of the plant, since it contains the apparatus for the regular propagation. But to this only two parts contribute—namely, the stamens, as generators and receptacles of the pollen; and the seed-bud or ovule, as the plant; namely, the Axis and accessory leaves, and stamens. The innermost part is occupied by organs which are formed from true axial organs, or an intimate blending of these with follicular organs, which are termed the female apparatus or the Leaf. All the internal parts of the flower—namely, the envelopes of the whole perianth, the calyx and corolla, the receptacies containing the seed-bud (the germans, styles, and stigmas), are not, in the Phanerogamia, axial, and they may be absent, without the flower losing its correspondence to the character by which a flower is defined.

In the correct (morphological) view of the flower, there is no distinction between essential and inessential forms, and therefore it is necessarily more proper to divide it into axial and follicular organs. The following relations should be borne in mind:—The axis and its modifications are the basis of the flower, because to them the follicular organs are attached. Attached to the outer part of the axis of the flower occur the several forms of the calyx and corolla, the leafy leaves, and stamens. The innermost part is occupied by organs which are formed from true axial organs, or an intimate blending of these with follicular organs, which are termed the female apparatus or the Leaf. All the internal parts of the flower. At the same time the parts of the flower are usually grouped together and treated generally, according to the relations of number and position, as well as of duration. Thus we obtain this plan for our following investigations:—

A. The Flower as a whole.
B. The number, relative position, and duration of the parts of the flower.
C. The true Foliar Organs of the Flower.
D. The Accessory Foliar Organs.
E. The Rudimentary Fruit.

A. The Pistil.
6. The Spermatophore.

The capsule has been called the male organ of a plant (with the superficious collective term Androecum); the Seed-Buds and their receptacle the Pistil, the female parts (together the Gynoecum). A flower that contains both parts is termed Hermaphrodite (Flies Hermaphrodites). Flowers with the ovaries only are termed Unisexual Flowers (Flores Unisexuales, Diclini). When, in the last case, male and female flowers (mas et femina) appear on the same individual plant, such plant is termed Monoecious (Planta Monoecia); when, in the same case, the individuals the plant is termed Dicous (Planta Dioica).

An Inflorescence which contains both male and female flowers, is also termed Inflorescet Amoronga. Here again it must be distinguished whether the male and female blossoms are formed upon different plans, as in the Capparidaceae (Diclines); or whether, through the suppression of one or other part, a pseudo-dichlinic condition appears in a flower formed on the plan of a hermaphrodite. This latter condition, which is never found to run through all the examples of any species of plant, brings monoeccies and dioecies species into hermaphrodites genera, and suggested to Linnaeus the establishment of his 32d class, Polyanthia, where in one and the same species male, and hermaphrodite flowers are present.

There are very few flowers of so simple a structure that they consist only of one simple essential part, so that no formation of internodes is possible within the flower; and the extremity of the pedicels immediately supports the floral parts. An example of this case in the Euphorbiaceae, where the end of a pedicel bears one single stamen; also in the male flower of the Abietinae, where one single foliar organ, converted into a stamen, constitutes the entire flower. It is also the case in the female flower of Tussa, where the small pedicel, clothed with bracts, terminates immediately in the naked seed-bud. In the generality of flowers however several parts are united which do not stand at equal heights on the axis, and thus more or fewer unites constituting the staminal or carpel structure of the flower. The original condition of the internodes, is here also most frequently permanent; and the pedicel, after the detachment of all the parts of the flower, frequently ends in a small slightly thickened knob, which represents the collective internodes of the flower in an undeveloped condition,—the simple base or receptacle of the flower (Torus). Examples in which individual internodes become elongated are rather rare. In some families they are elongated between the inner floral envelopes and the stamens (Androphorum), and in others between the flowers and the receptacle. The latter is generally termed Germin Stipitatum. There are examples of both in the Passifloraceae and the Capparidaceae.

A flower exceedingly longer part, without elongation of the individual internodes, frequently occurs as a gynophore in flowers which contain many germs (as in the Rosaceae, the Ranunculaceae, Magnolaceae, &c.) Again the gynophore is often presented as a hemispherical or cushion-like part, as in some other Rosaceae and Ranunculaceae. A very rare form of it is that of a reversed cone, which bears the germs upon a base turned upward, as in the Notobium. In the rarest instances, with the exception of this case, the axis of the flower is elongated within the floral parts even without ending as a germ; but this does sometimes occur, as in the male flowers of some Palms and other plants; for example Chamaedorea, where the points of the petals unite with the apex of the axis of the flower which passes up through them. In very crowded inflorescences, the torus of an axillary bud develops obliquely, and rises up on one side, especially beneath the germs, so as to appear as a part of its side-wall; this happens with most of the Grasses. A similar circumstance arising from a similar case, happens when many single germs arise only from one kind of the divisions of the torus, which forms the basis of each of those germs, and thus assumes the appearance of forming a part of the wall of the germ (as in Petautogonum and Dryadaceae).

Every other similar expansion of the internodes of the flowery bud immediate bear seed-buds, is called the Disc (Discus). This may be situated beneath the rudiment of the fruit (Discus Hypogynus), and then may be flat, as in Potentilla and Fragaria; or cup-shaped, as in Rosa, Populus (mas), &c. This latter may be free (Rosas), or may be united to the base of the stem (Discus Epigynus, etc.). It may pass off from the middle of the (half-)inferior germ (Discus Perigynus), as in many Myrtaceae; or, lastly, it may rise above the (inferior) germ, and stand upon it (Discus Epigynus). Here it is very rarely (or never) flat, but funnel-shaped (Discus Aglaé). It is sometimes termed the Germination or Germentus; or resembling a style, as in the Orchidaceae and Aristolochiaceae. In all these cases the foliar organs of the flower may be situated in very different places. Usually, indeed, they collectively form a zone around the edge of the disc; and when this disc is divided it may correspond to as many discs lying one above another as there are internodes implied by the number of foliar organs. Frequently the true foliar organs stand around the edge of the disc; and upon its inner surface the germs are arranged in one or more circles (as in Rosa, Panic., Oenagraceae). More rarely the floral envelopes alone stand on the border, while the stamens are then at a distance from them, upon an internal prolongation of the disc, as in the Orchidaceae.

The disc is by no means always regularly developed, but sometimes enlarged at one side only, whereby the whole flower appears oblique, thus in Rosaceae. The most remarkable structure is in Pelargonium, where the disc forms a shaving or leaf-like prolongation of the receptacle, in Tropaeolum, where the spur is formed solely by the disc.

There are but few special observations to be made respecting the structure of the internodes of the flower; it is in general like that of annual stems; and seems to be formed from a system of vascular bundles, and these of simpler development. The internodes (as also some of the foliar organs) within the flower, frequently do not have the epidermis developed, but, instead of this, a delicate soft and transparent integument exists, and, often containing a saccharine secretion, forms the investment of the surface (Nectarinn).

It is very rarely that a flower consists of one part only, as in the male flowers of Euphorbia, Leuca, and Wolffia, which are formed of one foliar organ, the author; or the female flower of Tussa, which is formed of one axial organ, the seed-bud. Usually more parts unite to form a flower: thus the female flower of most of the Araceae consists of one or more spiral foliar organs (a carpel surrounding the flower); the flower of the Salicaceae consists of a scale-like disc and some stamens. In the generality of cases, both male and female organs are present in the same flower: they are seldom naked, as in Hippuris, but usually surrounded by floral envelopes.

In axillary flowers, those parts which are turned towards the peduncle are termed the upper, and those turned towards the bract, where it is present, the lower. Some plants exhibit the peculiarity that the pedicel, until the time of the blooming, makes a half turn (analogously to the (male) stem), and it may be the true pedicel, as in Calcolorinia and some Orchidaceae; or the inferior germ, as in most of the Orchidaceae. By this curve, the upper parts of such a flower (in those plants the lip) become apparently the underside of each flower, and such flowers are termed Flores Aspersissimae. The term is sometimes falsely applied to some Orchidaceae in which no such twisting takes place, but in which the lip stands regularly as the upper part of the flower, as, for example, in Bletigia.

The individual organs of the flower taken generally, according to the common view, and known by collective names, may originally consist either of one piece or of more than one: in the first case they are parties monomers; in the second case parties diemer, triemer, or polymers. In either case the parts may be entirely separated and independent of one another, or they may be grown together in various ways. These coherent sets were formerly also called parties monomers, or monomers; later, diomers, triomers, or polyomers; and, as for example, Hemerocallis parthenium gamo- (mono-) phylum, hexamerum; Salvia, corolla gamo- (mono-) petals, pentamers; Rosa, corolla pentapetals, &c.

The coherence occurs here in the same manner as in the stem-leaves, but on account of the crowded position in the flower-bud, much more frequently. It happens either that
a single foliar organ grows together by its edges into a tubular or cup-like organ, as, for example, occurs frequently in the so-called monomeric floral envelope (Bracteole); or that several foliar organs grow together by their edges: this commonly affects all the edges of a circle of leaves, but sometimes two edges remain united, as with the calyx of Centaurea lutea. So, again, this process is usually simultaneous in development at all the edges of a circle; but it sometimes happens very much later,—a, on two uppermost leaves, that is, in one in which the petals and stamens are in the corolla of Torenia and the florets ligulati of the Composite; or, b, with each pair of leaf-edges at the side of the leaf-circle, whereby the two-tipped forms (petals bilabiata) of descriptive botanical arise. Another kind of blending also occurs in the twelfth leaves, which is an aggregation, or a double or a single calyx of Monocotyledons, Diadelphous, Polyadelphous. When the foliar organs of the flower are coherent, the blended part is termed the Tube (Tuba Perianthii, Calycis, Corollae, &c.); the free part is termed the Receptacle, or Vesica (Faux). One of the most striking examples of coherence, which also has no analogue in the stem-leaves, is found in the blending of the foliar organs of the flower at the point only, the union never extending further; so that the foliar organs, which are united at the base, are separate in the corolla of the male flowers of Chamaedorea, Canarina, and in the androspore of Symphyomena montanum (I).

Abortion in the flower means that some part present in the rudimentary condition is arrested during the development and growth up to a certain stage. It is not uncommon to come by observation. There is no other kind of abortion. So soon as the individual parts of a flower become distinct members, the foliar organs appear arranged around an ideal and real axis of the flower (the axis of the flower), and in the rudimentary condition always regularly. Through subsequent unequal development of the single parts, the flower frequently becomes unsymmetrical, or, as it is called, irregular. This irregularity is always such that the upper part of a flower becomes developed differently from the lower part, but the regularity very seldom affects the germ, which almost universally remains regular even in unsymmetrical flowers; yet there are cases in which this is the only symmetrical part, as in many of the Boraginaceae, Datura, and Caryocaraceae. In this classification, the coherence of its parts, is divided into two halves, an upper and under, developed in different ways, they are generally termed bilabiate; but if only one single foliar organ is developed this is relatively rarer; the corollas and innermost circles have usually fewer members. Again, respecting the number of circles which follow one another, no general state-ment of importance can be given. Seven different forms of foliar organs may possibly exist in the same flower, namely, the epicalyx, calyx, corolla, accessory corolla, the stamens, accessory stamens, and the carpels; but there is no flower in which all occur in conjunction. All these foliar organs may be present in one or more circles, with the exception of the epicalyx, in which there is no example of a double circle. Perianth, calyx, corolla, accessory corolla, and carpels occur in one, or more, or rarely in two circles. Stamens may be present, or, three, or possibly even four circles; more circles than this have not been exhibited in the flower. If the number is increased, which seldom happens except in stamens and carpels, as in Ranunculaceae and Dipsacaceae, the Magnoliaceae, &c., they stand no longer in groups, but in succession, with the exception of the perfect individualized flowers, with the single exception of some Scitamineae, five trimerous circles of foliar organs of the flower appear to be formed in those where a second circle of petals exists. The greatest multiplicity of forms occurs in the dicotyledonous plants. Lavoere, for example, has an epicalyx, calyx, corolla, stamens, and carpels in five circles, with increasing numbers of members; those of the calyx and corolla alone are equal. Gnadia vivens has perianth, stamens, accessory stamens, and carpels, but in eight circles, and in each circle there is an increase, both by no means necessary that all the parts of a circle of floral foliar organs should be ultimately developed in the same manner; and many floral structures which have hitherto appeared more or less mysterious, by discussing this truth in mind and following on the history of the development, be readily traced back to the original type.

The duration of the individual parts of the flower is very various; the axial organs, so far as they support the rudiment of the fruit, are permanent. While the flower is in full growth, and then to the ripening of the seed, then fall away with it; or if becomes disengaged from them, die away with the remainder of the plant. When axes bear only male organs, or flowers, their duration is different; sometimes they are cast off at a certain height, but generally they remain upon the parent plant, and gradually die away. The foliar organs of the flower are equally various in their duration. Perianth, corolla, and accessory corolla commonly perish soon after the perfecting of the flower; either they are cast off by true disarticulation, or they wither upon the parent plant. The epicalyx and the calyx frequently share the fate of the axial organs supporting the rudiments of the fruit; the carpels almost invariably. The carpels are rarely destroyed before the perfection of the flower; either they are cast off by true disarticulation, or they wither upon the parent plant. Robert Brown in Psalidotes Theta. The stamens die away almost immediately after the dispersion of the pollen; either they are cast off, or they dry up and die away within the flower.

The terminology in use is as follows:—Those parts which fall away immediately, when their perfect formation is but scarcely completed, are termed caducous or fugacious (partes caducae); those which endure somewhat longer are termed, when they are cast off, or deciduous (partes deciduae): if they retain their position, and die by gradual withering and drying up, marcescent (partes marcescentes); those parts which remain long, still vegetating, are termed persistent (partes persistentes); if they change their forms further growth they are termed exsert scent (partes exsertae).

As among the floral envelopes are usually reckoned the perianth, the calyx, and the corolla, we may also include here the epicalyx. Under the term perianth, in its narrowest sense, only the coverings of the flower persist after the ovum number, are applied closely to the flower and upon one level; so that all individual foliar organs on the axis of the flower, which only inclose stamens or germen, may be termed bract. All these bracts have this in common, that they are merely foliar organs peculiarly modified; and consequently all the peculiarities of form which occur in the latter naturally appear in the former also. It is not often that the leaves of the floral envelopes have great thickness; they are the most altered in form, the most useless. They answer to the petioles or peduncles are here frequent, much more so than in the case with the stem-leaves; and these are termed, according to their various resemblances to objects, cup-shaped, as in the lower petal of Pelopoda; hooded, as in the upper leaf of the perianth of Acetum; chaffy, as in so on. If a long sac-like appendage is formed at the basis of a perian-thal leaf expanded above, it is called a spur (calcar), as in
The formation of the spur is frequently conjoined with the formation of a symmetrical flower, where one upper or lower foliar organ forms a spur. The flattened expanded form, which is connected with the axis by a linear prolongation, frequently occurs in the sepals (t). This expanded surface is termed the limb or blade of the leaf (lamina); the narrowed base is not termed pediole but claw (unguis). True articulation is frequent between the base of the spur and the foliar organ. It generally occurs in the continuity of these leaves (t); therefore there are no true compound perianthial leaves, though a simply divided limb is frequent, as the petals palmitatiflora in *Ranunculus*, the petals pinnatifida in *Solanum*, and *Fuchsia*; it may probably be afforded in the separation of the upper part of the tube of the flower in *Mirtalobis*, of the calyx of the *Datura* from the lower, and in some similar cases.

True calyces are not met with in the floral envelopes, but appendages analogous to the ligula appear, which indeed a part of the structure described as the corona belongs. As in the *Narcissus* and the *Lycoris*, the scales of the throat of the *Boraginaceae* also belong here. These parts are formed in variously refined forms on the floral envelopes, and such appendages are sometimes exhibited standing upon the surface of the foliar organs, in three or more rows, one above another. Almost all parts recognized as corona and accessory corolla (paracorrina) belong here, in particular a part of the elegant form exhibited by the *Diascia*; so also does a portion of the so-called nectaris, as, for example, in the petals of *Ranunculus*. All these are more or less dependent appendages of the foliar organs, which are developed on the spur, so flat, all, or at least a portion of, being produced from them subsequently. Here also occurs the one-sided development of a corolla, this is seen in the petals of the *Apoxyopsis* (Vinca, Narium, and Cebora) the collective form of one or more circles, whether eother with one or other, or, in a more accurately designated, according to further peculiarities, as tubular (tubulosis), bell-shaped (campanulatum), funnel-shaped (infundibuliformes), salver-shaped (hypocrateriforme), rotate (rotatum), &c.

Five kinds of floral envelopes are easy to distinguish. When simple floral envelopes are either solitary or nearly similar developed in a circle of one evident form, colour, and structure, they are described under the general name of perianth, the single organs of which are called perianthial leaves. If in the floral envelopes of one flower we can distinguish two circles differing in form, colour, and structure, the outer is named the calyx, its component organs being sepals; while the inner is termed the corolla, its single parts petals. Then if three circles of forms are distinguishable the outermost is called the calyx, the middle of which is the corona, and the innermost phylla. When between the simple or multiform floral envelopes and the stamens other independent foliar organs occur which exhibit a structure very imperfect and abnormal compared with the envelopes, these are called a pammorphan corolla, of which it will be the object to speak further on, among the accessory parts of the flower.

The Perianth consists, according to the preceding considerations, of one or more circles of leaves, which are developed so as to be similar in colour, form, and structure. The following series of its forms may be more minutely characterized—

* The individual foliar organs are always expanded in a flattened form, seldom divided into limb and claw, and, at least occasionally, present a coherent, prominent, nutate, or ovate shape. They may be green, as in the male flower of *Urticaceae*, or of various colours, as in *Thymelaeae*; they may be firm and solid, and that especially when green, as in *Boraginaceae*; or of delicate texture, as in *Aristotylaceae*; or they may be developed as delicate filaments, or the innermost of which is very thin, as in the *Typhaceae* and *Canarium*. The perianth is almost universally regular, rarely (in some *Ranunculaceae* and *Orchidaceae*) symmetrical; in these cases never (t) 3 to 5 petals, or sometimes 10, and in *Diascia* it is then not unfrequently developed, hollow (concinnatum in *Acousmum*, calcaratum in *Orchidaceae*), and it is commonly the uppermost part of the leaf. The perianthic portions may be, as in *Solanaceae*; or coherent, as in *Fuchsia*, *Hemerocallaceae*; or the petals, as in *Urticaceae*; or of more, as in *Liaceae*. The petals are frequently blended with the stamens; in the coherent perianth the tube is sometimes straight, as in *Narcissus*; sometimes curved, as in *Aristolochia*. The mouth is mostly notched; sometimes, but seldom, as is the case in *Narcissus*, furnished with appendages which form a corona, which however are rare in the perianth, and in free foliar organs only (t) occur on the lip; the inner circle often has a beard.

The structure of Perianthial Leaves, is, on the whole, that of very simple leaves, which exhibit no special peculiarities, particularly if they are green. The ramifications of the vascular bundles are therefore simple, but an intercellular cavity occurs in the epidermis, usually. In the colored and delicate parts the cells of the parenchyma contain colouring matter. In general the parenchyma is very loose and almost spongy, often filled with various contents, and large intercellular cavities filled with air; hence the white colour. The epidermis is less developed in coloured leaves, and more resembles the structure of epithelium; stomata are sometimes present, especially upon the under surface, but the epidermal cells of the upper surface are all shorter or longer papille, which give the upper surface a peculiar velvety-like appearance. It is very frequent here to find the secreted layer of the epidermis (cuticle) regularly and delicately striated (stellulatum), which certainly contributes to heighten the brilliancy of the colour, and perhaps, by its effect upon the rays of light, to the production and modification of the peculiar tints.

Occasionally, especially at the base of hollow parts, no perianth is developed, but the leaf itself assumes a peculiar structure, to perform the function of secretion of a juice containing much sugar; as, for instance, the nectary at the base of the perianthial leaves of *Fritillaria*, very various parts on the labellum of the *Orchidaceae*, c. c. In these cases the differentiation of the stamens and carpels is not infrequently apparent in the intercession of many thickened porous parenchymatous cells, as in the species of *Bankia* and *Dyandra* (t). In paleaees perianthia the spiral and other vessels are not found in the usually simple vascular bundles, and in hairy perianthia even the vascular bundles themselves are wanting.

The Calyx only exists when a corolla occurs with it; it therefore can never be confounded with it. It is always the external of two dissimilar sets of envelopes. It is a series of perianthial leaves, often (in the *Boraginaceae*) it is not so frequently delicate in structure and colour, as in the *Scitamineae*, *Muscaceae*, *Butomaceae*, *Ranunculaceae*, *Tro- paeeae*, &c. Usually it consists of one circle of sepals, more rarely of two (as in the *Ranunculaceae*). These sepals are always very simple, oval, or lanceolate, seldom pinnatifid, very frequently broad at the base and tapering to a point, or very small (dentes calycis obsolete); sometimes they appear only as dry scales, or as tufts of hair (the pappus of the *Compositae*); sometimes they are androecious; in other cases they are frequently of hollow or concave form. The number of the sepals in each circle is in *Monocotyledons*, frequently three, more rarely four or two; in the *Dicotyledons* it is most frequently five, but also two, three, or four, and perhaps more in a certain number of cases. The number of the petals may occur in every way, but never with the corolla and stamens nor with the genems; that which is so called being quite another condition. Both in free and in coherent sepals, regularity and symmetry are met with; the latter often exhibit the bilabiate structures.

That which has been said of the structure of the perianth applies also to the calyx, only that here green foliaceous sepals are the more frequent.

The Calyx, as the inner set of floral envelopes accompanying a calyx, may be compared to a very delicate and colored perianth. No true corolla occurs perfectly green and resembling the leaves; its series of forms is greater than that of any other of the floral envelopes. In the *Ranunculaceae* it is composed of three, or four, or five, or perhaps more. The development of the sepal complex of the *sedalia* may occur in every way, but never with the corolla and stamens nor with the genems; that which is so called being quite another condition. Both in free and in coherent sepals, regularity and symmetry are met with; the latter often exhibit the bilabiate structures.

The individual petals exhibit, on a reduced scale and in a delicate condition, almost every variety of form of the leaf, with the exception of the truly compound. Concave forms are here frequent, such as the hood-shaped, petcher-shaped, and bell-shaped petals. Furthermore, there are to be found petals of an otherwise regular corolla, as in *Fritillaria*. Fringed and feathered forms, as well as variously lobed petals, are also by no means rare. The limb and the claw are often clearly to be distinguished. Parts analogous to...
the ligules, and every imaginable form of appendage, with the exception only of the stipules, occur frequently, and characterize genera and families.

On this account indispensible to distinguish the simple appendages of the petals from the independent foliar organs. To the former belong the scales (formulae) of the Boraginaceae, the scales of the corona of the Stellaria, the formations generally described as corons in the Scrophulariaceae and Polemoniaceae, the nectarias of Rorippa, Papaver, &c.

The corolla consists of one circle, rarely of two (three series in Berberis), or more (four series in Nymphaceae). In Monocotyledons the number of members is equal to those of the calyx, or to a multiple of it. In such cases the corolla is disposed symmetrically, but it is sometimes composed of two, or four, or of a greater number in Drysta. The number of members is equal to that of the calyx, or greater; very rarely indeed it is smaller; this last case occurs with Hibiscus. Supercorolla is not infrequent, and sometimes involves all the foliar organs of a corolla at once, as in the summer flowers of many species of Viola, Lepidium ruderale, and in some species of Acor. The coherence of organs in every way is still more frequent; never indeed with the case usually organized.

The corolla, whether with free or with coherent petals, may be regular or only symmetrical. In the latter the bilabiata formation is the most frequent, especially in five-flored species, in such cases the tube or throat of the petal is at the side, or under the side of the flower, the upper lip consists of three or of two petals. In the latter case these two are very often little or not at all coherent, as in Teucrium, the so-called radiated flowers of the Compositae (as in Helianthus); the true bilabiata or mouth-like corollas (corolla ringens), in which the petals form the upper lip often present a concave form overhanging the lower lip, termed gales; as in Calliopsis. In the former case the corolla is termed the standard (vexillum), whilst the lateral petals, as wings (alæ), are usually dissimilarly developed, and the two undermost, very frequently coherent, also developed unequally at the two sides, approach each other in a concave form, as so to form the keel (carina). Sometimes all the petals of the papilionaceous flowers become coherent at the lower part, and form a tube, as in Trifolium; or individual petals are abortive, &c. The most irregular of all the forms have received no name, and are all such as appear for instance in the Polygalaceae, the Basellinaeae, Tropaeolaceae, &c.

All that was said respecting the structure of the perianth holds also for the structure of the corolla, remembering only that this is more delicate. The corolla of the fives is very much in contrasting matter, and their distribution in genera is sometimes very remarkable. Very dense texture, in consequence of the presence of much-thickened porous cells, as in the Amaranthaceae, is infrequent. The structure of the epidermis, and its development into papille, hairs, &c. is very manifold. Development into surfaces secreting nectar, both at the bottom of concave forms and upon the appendages, is especially common. The petals also occasionally secrete a viscous substance, in consequence of which they appear of a milky white appearance. This happens at the points of the inner petals of the Pumariaeae.

The Epicalyx is seen where three separate series of foliar organs are distinguishable in the floral envelopes, and it is the outermost of these. There are not many plants which exhibit this series, and such appear for instance in the Polygalaceae, the Basellinaeae, Tropaeolaceae, &c. For an account of the other organs of the flower, see STAMENS, FRUIT, S. 2; STOMATA, SEED. For the functions of the flower, see REPRODUCTION IN PLANTS AND ANIMALS, S. 4.

(Schleiden, Principles of Scientific Botany.)

FOOD. The materials taken into the system of organised beings, and by which their functions are maintained, and out of which their bodies are formed, are called Food. Food in its widest sense is the raw material out of which plants and animals are manufactured. We shall confine ourselves here to the consideration of the food of animals, and of man in particular.

The great cause of the necessity of a constant supply of new matter or food to the body is the waste of the materials of which the blood and organs are composed, during the performance of their functions. The waste of this waste is seen in the form of the various excretions which are thrown off from the body by the skin, liver, kidneys, and bowels. We shall then, that the food, the blood, and the excretions, represent each other, that they contain substances of the same nature, and are all composed of the same ultimate elements.

If we take a portion of human flesh or blood, and seek for its ultimate elements, we shall find, that, on accurate analysis, they will yield the following elements:—

Few or none of these elements occur in the human body in their pure form, but are combined variously with one another, forming very different physical properties and chemical relations. These organic compounds may be divided, for physiological purposes, into two classes: the first four, carbon, hydrogen, oxygen, and nitrogen, being called organic, whilst the remainder are called inorganic elements. The first four are found universally present in plants and animals, and because animal cell and no vegetable cell can grow unless the whole of these elements exist. Hence, as they lie at the foundation of all organic existence, they are properly designated by this term.

The inorganic elements, though very generally present in large classes of animals and plants, are not universal. Man requires phosphorus and calcium in the form of phosphates of lime; for his teeth and bones, and the bones of the lower animals contain no phosphate of lime. Sea-animals and plants will not live without chlorine and sodium in the form of common salt; but fresh-water plants, and plants away from the sea-shore, do not require this constituent. The term inorganic, then, is applied to these elements to express their different relation to plants and animals, and will also point out their frequent occurrence in the mineral world. The elements of man's body however are all derived from the mineral world, and are identical with the same bodies in inorganic substances. The carbon found in the vegetable body is identical with that which forms, in its pure state, the diamond—which enters into the composition of graphite and various kinds of coal, and is found in limestone and chalk, forming a part of the limestone rock; and which, in the form of carbonic acid, is evolved by the burning of coal, of which these rocks are composed. The hydrogen of the human body is the same as the gas which, united with oxygen, forms water, and when combined with nitrogen produces ammonia. The oxygen of the animal is identical with the gas which, with nitrogen, forms as a fifth part of the atmosphere, and which, combined with the metals, forms oxides, of which the greater portion of the earth's surface is composed. The nitrogen of the organic world is identical with that which constitutes so large a portion of the atmosphere. Nor are these elements alone which constitute the human body in common with the animal and vegetable world, but they possess the same chemical properties, and that their agency in the human body depends on these properties. Thus, carbon and hydrogen are inflammable bodies, and have a great affinity for oxygen, with which they unite, forming carbonic acid gas: and water, the heat of combustion being given off in the process of union. This very process goes on in the animal body, and constitutes one of the most important functions of the body. The characteristic features of the functions and properties of animal and vegetable life depend on the chemical relations of the four organic elements.

These elements never enter the system in their pure form. Carbon, however needed in the animal frame, cannot be appropriated pure; and a man would starve with the Koh-i-Noor diamond. Plant food, therefore, cannot be used to advantage for more digestible forms of carbon. The gases hydrogen, oxygen, and nitrogen, would, any one of them in their pure state, destroy human life; and even when the two last are...
mixed with the atmosphere, they will not support life in that form. Again, we may mix them in various ways, and not be mistaken, for example, when combining with oxygen to form carbonic acid, and hydrogen combines with nitrogen to form ammonia, and these two compounds unite together to form common smelling-salts, or carbonate of ammonia. But small variations in the way in which they contain all the organic elements, will not serve for human food. Nevertheless what is not food for man is nutriment for plants. Carbonic acid and ammonia supply plants with materials of growth. It is from these two bodies that the vegetable kingdom elaborates all the substances which give to plants elegance in form, beauty of colour, deliciousness of scent, deadliness as poisons, and nutritionness as food. The plant stands between the mineral and animal kingdoms, preparing the former for the service of the latter. Without plants there could be no animals. This is one of nature's statements, and we are presented with no instance of an animal existing directly on mineral matter. It is true that many animals are carnivorous, and live on the flesh of lower animals. The lion and the tiger prey upon the deer and the antelope; but if we go one step further we still arrive at the vegetable kingdom as the source of animal nutrition. The deer and the antelope are herbivorous creatures, and the flesh of their body is formed directly from the plants they eat. So with the animals eaten by man, which are of that vegetable class, and supplied to man the materials they have obtained from the vegetable kingdom. At the same time the best standard we can take of food is milk, which is derived from the animal. When human milk is examined, it gives the following results in every 1000 parts:

These five constituents of milk may be regarded as typical of all kinds of food, whether obtained from the animal or vegetable kingdom. Hence we may class alimentary substances according as they are represented by one or other of these constituents of milk.

1. Aqueous. Water is required not only as the medium of conveying the other substances into the body, but it forms a permanent constituent of the body itself. Blood contains 790 parts of water to 210 parts of solid matter in every 1000. Muscles contain 770 parts of water to 230 parts of solid ingredients. The brain and bones contain about 937 parts of water in 1000. If food does not contain water naturally, it is taken into the system in the form of tea, coffee, beer, and also in its pure state. The quantity of water taken with the food should be about in the proportion of four to one, as we find it in milk. We cannot, however, judge of the quantity contained in solid food till we know its composition. Thus many substances which appear solid contain large quantities of water. In potatoes, for instance, there are 75 parts of water in every 100.

2. Oliginaceous. The butter of the milk represents oily and fatty matters in general, which seem to enter into the composition of all healthy food. They are taken by the inhabitants of tropical countries in the seed of the cocoa-nut, as well as by those of the polar regions from the fat of the seal and many kinds of fish. They are obtained from both the animal and vegetable kingdoms, being known by the name of suets, fats, and lard, from the former source, and oils and tallow from the latter.

3. Saccharina. The sugar of the milk represents several substances obtained from plants and used as food. Sugar itself varies in its composition according to its source; hence we have cane-sugar, grape-sugar, maple-sugar, &c. Sugar has also a composition near approaching that of starch, and this substance is very generally found in the vegetable diet of man; pure in the form of arrow-root, tapioca, and sago; combined in the flour of wheat and other cereals; in the eggs of animals; and the products of food, sugar is found alone in milk.

4. Proteinaceous. The casein of the milk, which, when separated, is known by the name of cheese, has in common with the other vegetable and animal substances, called fibrine and albumin, a certain basis name Protein. These substances form the chief part of the fabric of the body, and in their capacity of food perform a very different function in the body to the butter and sugar before mentioned.

5. Inorganic. The salts of milk are the saline substances which, entering into the composition of various parts of the human body, are necessary to its integrity and health. The importance of the presence of these substances is frequently overlooked in medicine, many diseases of the human frame arising from their absence. They are conveyed into the system in both animal and vegetable food; but in common salt we have an instance of a substance belonging to this class taken directly from the mineral kingdom as food without the intervention of the vegetable kingdom. In addition to these forms of dietetic substances found in milk, the food of the adult human being constantly contains certain principles which do not appear to be represented in the system. Thus, the substances called condiments, as the salt of the earth and wholesome spices, which although not essential to the diet of man, seem to exert a very beneficial influence when taken into the system. In tea and coffee there is a principle called theine, which seems to be the active ingredient of these substances. In the fruit of plants also, we have acids, as the citric, tartaric, malic, and oxalic acids, which seem to act very beneficially in certain states of the system. As these substances seem to act medicinally rather than dietetically, they may be properly called, as a class, the inorganic constituents of food. The following classification will give an idea of the kinds of food:

Class I. Alimentary Substances.

Group A. Aqueous, containing water as a principal ingredient.

Examples:—Tea, coffee, beer, wine.

Group B. Carbonaceous, containing carbon as a distinguishing ingredient.

1. Saccharina. Examples:—Sugar, starch, cellulose.

2. Oliginaceous. Examples:—Oil, butter, fat.

Group C. Nitrogenous, containing nitrogen as a distinguishing feature.

1. Vegetable. Examples:—Flour, oatmeal, maize.

Group D. Inorganic.

1. From organic sources. Examples:—Potash in fresh vegetables, phosphates of lime in flour and flesh.

2. From the mineral kingdom. Example:—Common salt.

Class II. Medicinal Substances.

Group A. Acida. Examples:—Citric acid in oranges, tartaric acid in grapes, oxalic acid in rhubarb-leaves.

Group B. Volutile Oils. Examples:—Mustard, pepper, nutmeg, cloves.

Group C. Alkaloids. Examples:—Theine in tea and coffee, thebromine in chocolate.

We shall here make a few general remarks on the nature of the substances in the groups indicated, referring for special information on the plants and animals yielding food to the supplements referred to these subjects throughout the Cyclopaedia, and its Supplements.

Under the head of Water we shall find an account of Water and the substances it usually holds in solution. In taking it as an article of diet, the following general remarks should be borne in mind:

First, it may be taken in too large quantities to be carried off by the other excretory organs, and then it remains in the system to impoverish the blood, and to reduce the amount of solid matter that is necessary for the performance of the functions of the tissues of the body. This is one of the results that take place from what is called the 'water cure.' Unless persons have sufficient vigour to take the exercise necessary to throw off by the skin the water that is taken into the system, it will effect necessity arise. The good that is effected by this system on the treatment of certain diseases must be attributed more to the exercise it renders necessary than to the unnatural quantities of water taken into the system.

Secondly, water may not be taken in sufficient quantities to carry on the healthy functions of the system. If the food is taken too dry, it is only imperfectly digested, and many important constituents, such as the salts, are not taken into the body in sufficient quantity. A deficient quantity of water in the blood will also prevent the healthy action of the kidneys, and waste and degeneration of the solid parts of the body.
high temperature a gelatinous mass, explains the change which takes place in boiling the flour of the grains in which it is contained.

Starch is found in some plants in greater quantities than in others; it is very generally found in perennial roots and rootstocks, in the stems and in the seeds of plants. There are few or no vegetables or parts of plants that are eaten that do not contain starch. It is found in turnips, carrots, potatoes, cabbages, parsnips, beans, peas, wheat, barley, oats, and the tubers of Commelina, lilies, herbs, mint, haxl-mint, and all other seeds; in the apple, the pear, the plum, and cherry, and all other fruits. In many of these things however it is not the distinguishing alimentary ingre-dient, but it is a component part, and only as such is starch considered as an article of diet. The substances in which it occurs pure are arrow-root, sago, and tapioca.

What is sold under the name of arrow-root in the shops, is a form of starch procured from the rootstocks of various species of plants belonging to the family Marzamaceae. The three kinds of arrow-root known in the shops, the West Indian and the East Indian arrow-roots, and Tons les Mois.

Although there is much difference in the price of arrow-root, its composition is always the same. Even the substances used to adulterate arrow-root, such as starch, and sago starch, are of the same composition; and though the appearance and flavour of the arrow-root may be impaired, its ultimate dietetical action is the same.

Although tapioca and potato starch, are all composed of the same constituent, their flavour is very different; hence the preference given to arrow-root as an article of diet. This flavour depends on some peculiar prin-ciple which is produced in the plant from which the starch is derived, and is conducive to the health. It is not found in the rid of Arrow-root is used for making cakes, puddings, and a thick gelatinous fluid in great request in the sick room. It is a property of starch to combine with water at a tempera-ture of 100° and form a gelatinous compound. This pro-perty of starch renders it very useful in cookery, and seems to increase the digestibility of the starch itself.

Arrow-root is frequently regarded as nutritious; but it will be seen that it is not nutritious in the proper sense of the word. These foods can alone be called nutritious which contribute to the building up of the fabric of the body by adding those materials to the tissues which are being con-stantly removed by the wear of the body. Now starch does not perform this function, and is entirely consumed in the body in maintaining its animal heat. Arrow-root however and the other forms of starch, are frequently mixed with nutritive matters, such as milk and bread; and in this way the food into which they enter becomes nutritious.

Sago is the other and another kind of starch obtained from the inside of the trunks of palms, and other trees. Many plants yield starch in their stems, which, on being prepared, is called sago by Europeans. The sago which is sold in the shops of England is principally imported from the islands of the East Indian archipelego. These foods can alone be called nutritious which contribute to the building up of the fabric of the body by adding those materials to the tissues which are being con-stantly removed by the wear of the body. Now starch does not perform this function, and is entirely consumed in the body in maintaining its animal heat. Arrow-root however and the other forms of starch, are frequently mixed with nutritive matters, such as milk and bread; and in this way the food into which they enter becomes nutritious.

Sago is not generally so carefully prepared as arrow-root, and it is a much cheaper article of diet. Its ultimate action is perfectly the same as arrow-root. It is now often employed by starch-makers to procure the finer kinds of starch. When thus prepared, it is used to adulterate arrow-root.

Tapioca is another form of starch. It is brought to Europe from South America, and is the produce of a plant known to botanists by the name of Manihot Eschsch. It is poisonous in other forms, and is converted into a starch by extracting a poison from it, which they use to poison their arrows, before they obtain the starch. Cassava, which is eaten by the natives, is procured from the same plant, but is prepared in a very different way. It is converted into a starch by a process which is different in chemical composition from that of sago and arrow-root, and it is used in the same way, and for the same purposes.

There are many other well-known plants which owe their dietaetical properties to the starch they contain; amongst these we may instance the potato, the cabbage, the turnip, the parsnip, the carrot, the radish, the salsify, the chicory, the Jerusalem artichoke. From any of these starch might be prepared. The roots of Arum maculatum, though acrid, contain much starch. When cooked, the seridity of the plant is got rid of, and they are
eaten with impunity. These roots are employed in making the substance called Portland sago, which is the starch separated from the rest of the matter of the plant. This sago is used for the same purposes as the other kinds of sago.

The roots of Orchis mascula, which is a common plant of our meadows, form the substance called sable. When it is boiled, it forms an agreeable article of diet, which, before the introduction of tea and coffee, was very generally used in this country. It is now almost entirely dispensed with in Great Britain.

Starch differs in some of its chemical and physical properties according to the plants whence it is obtained. In this country, the Starch of the Artichoke (Helianthus), which is fed on by the hares, is a form of starch obtained from the Inula Helianthium, a plant not uncommon in our own fields. Lichen-starch is another form, which is found in almost all kinds of Algae as well as Lichens. This starch has the same power of thickening water at a high temperature as potato-starch and tapioca; and hence, when any of these plants are boiled in water, they form a thick mucilaginous decoction. - The thickness of the fluid thus obtained, under the erroneous notion of its being nutritious, has led to the use of many species of sea-weeds and lichens as articles of diet.

One of the plants of this kind, which has been used most extensively and is still largely employed, is the Iceland-Moss (Cetraria Islandica). It belongs to the family of Lichens, and is a native of the northern parts of Europe. This plant, and other lichens probably contain other dietical secretions besides starch, as we find they are capable of supporting animal life. The Reindeer-Moss (Cetrannce rupestris) is an instance of this. In the northern parts of the world as well as in our own mountainous districts this lichen grows in great abundance, and during the winter season is the principal support of the reindeer. In spite of the extreme cold to which it is subjected, this plant grows with vigour, and the rein-deer, in order to obtain it as food, is obliged to remove with its nose the snow with which it is sometimes covered for many feet. The Cup-Moss (Cenomyce pyxidata) of our own moors belongs to the same genus as the reindeer-moss, and is also used as an article of diet in the same way as the Iceland-Moss.

The Tripe de Roche is another of these lichens which has been long considered in Europe. It has a melancholy interest attached to it, as it has so often formed the chief article of diet of our arctic navigators. Two species of lichens, the Gyrophora procumbens and C. croce, afford the Tripe de Roche. Although they are said to be nutritious, they are described as having bitter, nauseous, and putrefactive properties.

Amongst the sea-weeds which have been used as articles of diet none is better known than the Chondrus crispus, which is the Carageen, and the Chondrilla norvegica, the Pearl-Moss, which has been for a long time used in Europe. It grows on the rocky shores of Europe; and when washed and dried, and then boiled with water, makes a mucilaginous decoction, which, like the preparation of the Iceland-moss, has been recommended for use in diarrhoea, cholera, coughs, and diarrhoea, and other diseases. It has however no bitter principle, and is probably less tonic than the lichen. This and other sea-weeds have been occasionally had recourse to by the poor inhabitants of the seas-shores of Europe, more especially Ireland, when the ordinary corn or potato crop has failed. They contain however but little nutritious matter, and persons soon famish who live upon nothing else.

There are several species of sea-weeds which are often eaten as an addition to other food. Of all these the Laminaria, as a certain flavour of the sea, arising probably from the saline matter they contain, which renders them very objectionable to some persons as articles of food, and which will probably always form an objection to their general use. Of those which are eaten in various parts of England we may mention:-

1. Laver, Sike, Siskum (Porphyra laciniata). It is on all sea-shores; and when employed as food is salted and eaten with oil in the north of Ireland, and in the West of Scotland.

2. Green Laver, Green Sike, Oyster-Green (Ulva latissima). The Ulva is not so good to eat as the Porphyra, and is only had recourse to when the latter is not abundant.

3. Bally-Sea, Sea-Ordles, Blue-Wand, Red Ware (Laminaria digitata). It is cooked by boiling for a long time, and adding pepper, butter, and lemon-juice. Cattle are fed on it when young in some parts of the British islands.

4. Redderyches, Hen-Ware, Honey-Ware, Marline (Alaria esculenta). The part of the plant which is eaten is the think middle rib which runs through the frond. It is sometimes called the Estable Fucus.

5. The Dulse of the south-west of England is the Fucus undulates of botanists. It is eaten by the fishermen of the south-west coasts of England, who before eating it pinch it between red-hot forks. In Scotland it is cooked in the frying-pan.

6. Dulse of the Scutch, Dullerk, Dulliel, Duleig, Water-Leaf (Rhodomenia palmata). The Highlanders and the Irish, before the introduction of tobacco, were in the habit of drying this weed and using it as a masticatory. The plant is fed on as an article of diet under the name of the Sugar-Fucus. In the islands of the Mediterranean Archipelago it is employed as an ingredient to flavour soups, ragouts, and other dishes.

Several other sea-weeds have been employed as food, but generally the principal that are at present used in this country. In Obana the people are very fond of sea-weeds, and many kinds are collected and added to soups, or are eaten alone with sauce. One of these, the Plocaria tenac, if sometimes brought to this country under the name of Chinese Moss. The detection it makes is so thick that it is used as glue. The Cornicul Moss, which has a reputation in medicine as well as a diet, is the Plocaria Helminthocactus, and is found on the coasts of the Mediterranean. Another form of sea-weed is the humicaria which is exported in some quantity from the coast of Australian Moss; but although affording a very thick jelly, it tastes too strongly of the sea to be rendered pleasant by any kind of cooking.

The next dietical substance of which we have to speak is Sugar, which is readily found from the sea by various properties. Sugar is soluble in water, whilst starch is only digestible through it. Sugar is susceptible of fermentation, and of being converted into alcohol, which starch is not. Sugar has a peculiar sweet taste, whilst starch is insipid. It is on this account that a species of sugar is found in the south-west of Scotland, and in other parts, which, so very seldom, find it in plants in a solid condition. It is always dissolved in the water naturally contained in the plants in which it exists. Sugar is not so frequent a product of vegetable change as starch; but it is, nevertheless, very generally found during some period of the growth of the majority of plants.

Sugar, like starch, is not nutritious, but is taken into the system with the object of maintaining animal heat. Persons may even get fat on sugar, but it is most perhaps nourished by any of the carbonaceous productions of plants. It is true, that in countries where the sugar-cane is grown, slaves and their children, during the period of its gathering, partake of it in large quantities, and are nourished upon it; but it is to this system of economy, and the consequent other alimentary principles besides sugar, which assist in the nutrition of the body.

Sugar, being readily soluble in water, is more digestible than starch. Of the substances which maintain animal heat, it is one of those substances which does not undergo any reason why it is supplied to the young of the higher forms of animals. For this purpose it is secreted, by the female of all the Marsupiata, in the milk, which is furnished universally to their young during the first months of their existence. The instinctive love of sugar, so well known as a distinguishing character of the child, seems to point out its adaptation to the wants of the infant system. Readily digestible however as sugar is, it is one of those substances which is converted into fats in the stomach; and when we consider how the stomach and the system, its elements seem to enter into secondary combinations, which are very injurious. This is why so many persons find it necessary to limit the quantity of sugar which they take in their diet. The changes how ever which proceed the most readily understood, and the way in which each of the atoms of sugar are not do appear to take place in children; hence the child may eat sugar with impunity, although its parents may not.

Although there are various kinds of sugar, having a different degree of sweetness, and oil and sugar would seem to act diestically in the same way upon the system. The most common is sugar of plants, and that which is most frequently eaten in diet, is Cane-Sugar, so called from its being yielded by the sugar-cane. It consists of-

<table>
<thead>

</thead>
<tbody>
<tr>
<td>Carbon</td>
<td>12</td>
</tr>
<tr>
<td>Hydrogen</td>
<td>12</td>
</tr>
<tr>
<td>Oxygen</td>
<td>9</td>
</tr>
<tr>
<td>Water</td>
<td>9</td>
</tr>
</tbody>
</table>
The other kinds of sugar which are eaten, are milk-sugar, \( \text{C}_\text{6}\text{H}_\text{12}\text{O}_\text{6} \cdot \text{H}_\text{2} \text{O} \); and grape-sugar, \( \text{C}_\text{6}\text{H}_\text{12}\text{O}_\text{6} \cdot 2 \text{H}_\text{2} \text{O} \). It will be seen that the cane-sugar resembles starch in its position, and it is probably formed in the plant from that body. Although cane-sugar is found in the sugar-cane, the beet, and the maple, it is not so frequent in plants as grape-sugar, which is the form in which sugar is found in the fruits and parts of the plants which may be called fruits.

The sources of sugar, as an article of diet, are of course very various; it is only separated however from a limited number of plants. Of these the principal is the Sugar-Cane (Saccharum officinarum L.), the cultivation of which by the inhabitants of France is principally obtained from the Beet (Beta vulgaris). In tropical countries it is obtained from the juice of palms, as from the Jaggery Palm (Carpopterus urens), the Cocoos-Nut Palm (Cocos macrofura), and others. It exists in the sterna of all grains, and is prepared in America, from Mazo (Acor Myers). The Birch (Betula alba) in this country, and the Sugar-Maple in America (Acer saccharinum), also yield it in their sap.

Grape-sugar, also called Glucose, is found in the fruits of most plants, and it is to act on the system in precisely the same way as cane-sugar.

The result of the fermentation of grape-sugar is the production of Alcohol, which does not differ much in composition from sugar. The following is the decomposition:

\[
\begin{align*}
\text{Alcohol} & = 2 \text{Atoms of Carbon} + 2 \text{Atoms of Hydrogen} \\
\text{Water} & = 2 \text{Atoms of Hydrogen} + 1 \text{Atom of Oxygen}
\end{align*}
\]

One Atom of Grape-Sugar = 12 14 12

Alcohol is taken as an article of diet in the form of beers, wines, and spirits. Although resembling sugar in its composition, its effects on the system are very different. It acts on the nervous system as a stimulant and sedative; and it might perhaps be regarded as one of the medicinal forms of food. A question has arisen amongst physiologists as to the action of this substance on the system. Liebig, and with him many others, maintain, that, like starch and sugar and all, the food is part taken up by the system, and thus by combustion assist in maintaining animal heat. On the other hand Dr. Carpenter, and those who repudiate the use of alcohol in diet, maintain that it is not destroyed during respiration, and consequently does not promote animal heat any further than it stimulates the heart's action.

Alcohol when taken as an article of diet not only acts upon the nervous system, but on account of its chemical action on albumen exerts an injurious influence when taken in large quantities, and is the cause of the so-called pot-stomach. It is thus that when indulged in, it becomes a source of indigestion, and lays the foundation of serious diseases. Taken in small quantities in the form of wine or beer, it seems to exert a beneficial influence on the digestive functions, and to belong to that class of foods to which spices and condiments are referred. Taken medicinally it is often capable of exerting powerful effects, on account of its resorting action upon the vascular system. It does not seem to be necessary to health, as there are many nations that never use it, and individuals, in countries where it is habitually taken as an article of diet, find their health not materially injured by forbearing themselves from its use.

The quantity of alcohol contained in fermented beverages varies very much.

With regard to wines, when the juice of the grape contains large quantities of sugar in comparison with the water, and the fermentation is complete, than the alcohol is abundant, and strong wines are produced; whilst when the sugar is in small quantities, or the fermentation is incomplete, weak or thin wines are the result. Ports and sherrys are strong wines, whilst those of the Rhine are generally weak.

Sweet wines are those in which all the sugar is not converted into alcohol, and come from grapes other than those made from other fruits besides grapes. Hence the well-known sweetness of what are called British wines. This does not however arise from an imperfect fermentation, but from the acid contained in other fruits not being tarteate of bicarbonate of lime, which has the property of preserving the insaline salt (the cream of tartar) with potash, which is generally found in fruits; and in wines made from the grape this salt falls to the bottom of the cask, forming the tarter or less of the wine. But other acids, as citric, malic, and oxalic acids, are not thus precipitated from their solutions, and they remain in wines, giving them a very acid flavour, which would render them unpleasant, unless sugar was added to cover their acidity. Sweet wines are objectionable as articles of diet, on account of the sugar they contain, which, when held in solution in wine, seems more likely to decompose, and thus prove injurious to the system than when it has been in its pure form. In wines made from other fruits besides grapes, the acid is also liable to objection.

Efferescent wines are those which are bottled before the fermentation is complete, so that a large quantity of the carbonic acid, which is the other constituent of the wine, is still in solution in the wine, and escapes when the bottle is uncorked. Such is champagne. Efferescent wines are more liable to disagree with delicate stomachs than others, on account of their imperfect fermentation rendering them liable to further change in the stomach; and this change is probably communicated to the substances used as food contained in the stomach.

The skins and stalks of the grapes, if not the juice, contain alcohol. This substance is a pure extract of alcohol, and its presence seems to be the cause of the astringent character of many red wines, as port, claret, and others. There is also a difference in the quantity of free tartaric acid contained in wines; and those which have the largest proportion of this constituent of the wine, are least likely to change from grapes are so sour as to be very unpalatable; this is more especially the case with the poorer white wines of the Rhine.

The quantity in which wines differ from each other most is what is called their bouquet, or flavour. It differs in wines made from different kinds of grapes, and differs in the same grape in different districts and in different seasons. It is well known that the vintage of one year produces a better or worse wine from the same grape, and this depends on the development of the peculiar flavour of the fruit of alcohol. As such, it might be regarded as a bouquet which is independent on an acid which he calls enanthetic, and which, combining with the alcohol, forms an other which gives the odour and flavour to wines.

The quantity of spirit in wines varies very much. The ports and sherrys consumed in England contain the largest quantity. But then much of this is added. It is added in the form of brandy. Brandy wines keep best, but are not the best to drink. Unless wines are naturally strong, they will not keep without some spirit added. Clarics, hocks, and Moselles, are seldom brandied. Some of the hocks do not contain more than seven per cent. of alcohol, whilst port and sherry contain twenty-five per cent.

Ardent spirits, distilled liquors, derive from wine in their having been part distilled with the wine, which produces the alcohol. Brandy is distilled from wine; and pech-kernels, or other vegetable matter containing oil of bitter almonds, are added to give it a flavour. All the rums are the product of the sugar-cane, the Rosaces, called Amygdalin, contain oil of bitter almonds. Rum is distilled from molasses or treacle in the West Indian, and pine-apples are added to give a peculiar flavour. Gin is distilled in Holland, from rye; in this country from wheat, the grains of which are allowed to become saccharine, and then fermented. Juniper berries are employed to give the peculiar flavour to gin. Whiskey is distilled from wheat, barley, or oats, treated in the same manner as for gin. Nothing is added to flavour it; but the smoke of the peat is used to give the colour. The following introduces a slight but distinct difference between Irish and Scotland, gives a characteristic flavour to this liquor. Liqueurs belong to this division; they are distilled spirits containing large quantities of sugar, and are flavoured with all kinds of substances, as celery, bitter almonds, gentian, wormwood, &c.

Beers, ales, and porters, differ from wines in the addition of a bitter principle, most frequently the hop, to the fermented liquor. The saccharine matter for fermentation is thus obtained there from. The hops are added after the water, and allowed to germinate. When the starch of the grain is converted into sugar, it is submitted to heat, and malt is formed. The malt is placed in boiling water, and hops added; when cooled, the process of fermentation is allowed to take place, and the beer is complete. As the malt is slightly charred during the process of drying, it gives a dark colour to the beer. It is then called porter. These fluids vary much in strength and bitterness, according to the quantity of malt and hops employed.
Beer is the safest of these beverages for habitual use; but even this may be indulged in too freely, and disease may be the result. Of the various kinds of beer, that which is to be most commended, is the weak form of bitter ale, which is now so generally employed in the households of London and other large cities as a tonic on account of its bitter principle, as well as a stimulant, and is frequently, on this account, found to be a valuable addition to the ordinary diet.

The Oligoeclon group of foods is somewhat peculiar. They are taken in various forms from both the vegetable and animal kingdoms, and are known under the name of butter, oil, lard, suet, fat, &c. The following formula will express the composition of this class of bodies:

<table>
<thead>
<tr>
<th>Carbon</th>
<th>Hydrogen</th>
<th>Oxygen</th>
</tr>
</thead>
<tbody>
<tr>
<td>11</td>
<td>10</td>
<td>1</td>
</tr>
</tbody>
</table>

It will be seen that the oxygen is in considerably less proportion than in the foregoing substance of this group, and we may consequently conclude that the hydrogen as well as the carbon is consumed in the system in maintaining the animal heat. This is an important point, as it frequently happens that the value of the heat-giving properties of foods is diminished by the quantity of carbon alone. That oil has more power in maintaining animal heat than sugar or starch, is seen in the fact that it is eaten in larger quantities by men who live in cold regions than by those who live in the warmer parts of the earth. Just as the fruit from the tropics, man adds oil to his food according to the degree of cold to which he is exposed.

Oil seems also to be deposited in the tissues of man and other animals as a source of combustible materials when those derived from the vegetable kingdom alone are insufficient. The vegetable fat is appropriated by the fat in summer to supply them with their winter's store of fuel. Nybeytating animals, which are fat when they commence their sleep, wake up quite thin. Their fat has been exhausted in maintaining their animal heat, during hibernation.

Oil performs another function in the system. It is very evident from its general presence in every tissue of the body that it has an action in connection with the development of the protoplasmatic tissues. It seems to assist their development, to act as a kind of preparation for their growth. In this way its curative action in certain forms of disease may be explained. There is no doubt of the beneficial action of cod-liver oil in scrofulous diseases, and its action can only be explained on the above supposition. In connection with the use of cod-liver oil it may be stated that animal oils appear to be in a different physical condition of aggregation from vegetable oils, and are certainly more readily digested and assimilated by the system.

The vegetable oils chiefly used as food are those obtained from the Olive (Olea Europaea) and the Almond (Amygdalus dulcis). Many seeds, as the Cocoa-Nut (Cocos nucifera), Almond (Amygdalus), Chestnut (Castanea), Walnut (Juglans), Brazil-Nut (Carylus), Brazil-Nut (Bertholletia), contain oil.

The fat of animals is the great source of oleaginous food from the animal kingdom. We now come to speak of the Nutritious, Prototannaceae, or Nitrogenous articles of diet. The substance called Protein is the basis of these. It is the first element that appears in the development of the vegetable cell. It is consequently universally present in plants. It also constitutes the chief and essential element of the protoplasm of both kingdoms various forms, and is called albumen, fibrine, and casein, according to its physical and chemical properties.

Some animals derive this constituent of their bodies directly from the vegetable kingdom, as all the herbivorous and granivorous creatures derive it indirectly from the plant through the animal, as the various forms of Carnivora. Man obtains his supply of protein from both sources. As a sect has arisen of persons who deny the presence of the so-called "protein" in vegetable food, it may be well for us to examine the evidence on which their claim to be regarded as a flesh-eating animals rests. We shall dismiss the sentimental objection, that life ought not to be taken as unworthy of serious notice, and every one must feel that for carnivorous animals to prey upon lower animals is a natural law, as well as a practice is universal, and it is precisely amongst these people that we see the greatest amount of physical power, and moral and intellectual development existing. Amongst these nations, those individuals and classes who partake most largely of or are entirely a vegetable diet, are not only physically, and morally degraded. It is a well established fact, that amongst those classes who get the least animal food, as also in those public establishments where meat is only sparingly allowed, mortality is greatest, and disease is the most common. One of the most common symptoms of disease is manifested by an exclusively vegetable diet is scurifals, and when traceable to this cause, the most speedy remedy is the addition of animal food to the diet. There are also many other forms of disease produced by the want of animal food, which are not the disease of man's body but an abundant supply of the needed material. I need not, I am sure, specify facts to verify this statement. The experience of every medical man would confirm it, and there is no surgeon or physician connected with the structure of man's complex mechanism, who has every day, unfortunately, ample opportunities of witnessing the ill-effects of a vegetable diet, and the benefit, in such cases, of the administration of animal food.

"Nor are we at a loss in accounting for the beneficial action of the flesh of animals as food. From what I have before said, it will be recollected that the muscles and other tissues of animals are composed principally of protein; so that they truly constitute the most nutritious kind of diet. It has also been found, not alone as a matter of general perusal, that the most carnivorous animals are the healthiest and most digestible than vegetable food. The experiments to which I allude are those performed by Dr. Beaumont of America, on a man that had received a gun-shot wound in the stomach. The man lived 10 years, and we are all of the opinion that this wound never healed, and, enabled Dr. Beaumont to perform the experiments alluded to. By placing various kinds of food in the stomach of this man, he was enabled to ascertain how long each required to digest; and it was found that the flesh of animals is much sooner digested than the more nutritious forms of vegetable food, as bread, and the preparations of flour.

"Could we not find reasons for partaking of animal food in its nutritiousness and digestibility, we might find ample justification for the structure of men by comparing man with the lower animals. To the comparative anatomist it is sufficient that he knows the structure of the teeth, jaws, or stomach of an animal, to tell whether it fed on vegetable or animal food; and when he has once determined the structure that characterises the one or the other combined, he will know that the animal will require both kinds of food. Let us, then, for one moment glance at the structure of the teeth, jaws, and stomach of vegetable-feasting animals, and compare them with the structure of man. It is hardly necessary to assign animals of the ruminant class, as the sheep and the ox, as specimens of pure vegetable-fed animals. On examining their teeth it will be found that they have broad surfaces, made rough for the purpose of rubbing on each other, and between those surfaces, and they eat something which causes them to be swallowed. In order that these teeth may be moved with facility over each other, the jaw, in addition to the up and down movement, which is essential to the reception of the food into the mouth, has a lateral movement, by which the triturating of the food between the teeth may be effected. The tooth thus prepared passes down a long esophagus, or gullet, into a complicated bag or stomach. In the ruminants, though not in all the vegetable-eating animals, a process of further digestion, called fermentation, takes place in the stomach, as the mastication of the food between the teeth, and its ultimate digestion in the stomach.

"If we turn now to the structure of flesh-eating animals, of which the Carnivora, embracing such animals as the lion, and lioness, as well as the ferret, racoon, wolf, and hound, must be excluded, which have long teeth furnished with broad surfaces, they have teeth with sharp points for holding and cutting their food. Their lower jaw has no lateral movement, but a powerful up and down action, which is sufficient to enable them to tear off the flesh in pieces and make them into small bits, by which the tooth is made to act in dividing their food, something in the way of the blades of a pair of scissors when used in cutting. In passing to the stomach, we find the gullet short, and the stomach small and simple in its form, adapted for that food that is readily digested, and is such as has been referred to as a vegetable diet.

"On an examination of these organs in man, it will be found that they are a true mixture of these two classes. His teeth are partly adapted for grinding, while in some of
them are supplied with the sharp projections which are characteristic of the Cornea; thus evidently adapting them for the mastication of both vegetable and animal food. A slight lateral movement of the jaw being continued, the downward action is expressive of the suberviciency of its structure to a mixed diet. In the stomach also we find indications of the same intermediate position in its structure; and the same conclusion is forced upon us, that it is part of the apparatus of digestion dependent upon a diet composed of animal and vegetable substances.

"That man can live on food derived entirely from plants, or entirely from animals, is a well known fact. The natives of many parts of Asia never eat animals; whilst the Hottentots of the Cape of Good Hope, and the aborigines of the northern part of the world, and the Guachos of the Pampas of America, seldom or never have vegetable food; but neither the physical, moral, nor social condition of either the one or the other will prompt the suggestion that man attains his highest development exclusively on either vegetable or animal diet. In the various positions in which man is placed in the world, there can be no doubt that the relative quantities of flesh to food derived from plants, may vary much with great advantage; but there seems to be no position in which man in health can be pronounced to be the better with abstinence from either the one or the other kind of food. That man does subsist on either exclusively only proves the great range of his adaptability, and it is not improbable that it is possible to plant it on the surface of the earth; but certainly it is no proof of his labouring under a necessity for the supply of one to the exclusion of the other." (Lankester, 'Letters on Diet'.)

Of the three forms of protein referred to above, fibrous is found in the flesh and blood of all animals, as gluten in wheat, barley, oats, rye, and the other Cereals. Albumen is found in the juices of many plants, as cabbage, cauliflower, asparagus, &c.; and also found in the nervous system and blood of animals. Casein is present in milk, also in the seeds of leguminous plants, as peas, beans, and lentils.

In the animal body a substance called Gelatin, which appears to be formed out of the proteinaceous tissues. This substance is found in all the vital organs of the body, and what cellulose is in the vegetable kingdom, gelatin appears to be in the animal kingdom. Although often taken into the system with animal food, especially in soups and jellys, there appears to be no evidence that it is ever converted into a proteinaceous tissue. Experiments on this subject have been performed both in France and Belgium on an extensive scale, and the conclusion arrived at was the same, that gelatin is not used for forming any of the proteinaceous tissues. It is generally held, however, impossible that the gelatin may be appropriated for the purpose of renewing the gelatinous portions of the tissues, which are very extensive in the animal body. It will be thus seen that although gelatin cannot be said to be necessary for the vital organs, it is an actively vital part of the body, and may in its absence not only cause the death of the body, but also prevent the restoration of a future existence.

Of the forms of protein which occur in food, Casein demands a short notice. Although, as dissolved in milk, it is a very digestible it becomes, when in an unabsorbed state, the cause of indigestibility. When milk is deprived of its butter, and the pure casein made into cheese, it is the case with some English cheeses, as those from Suffolck, it becomes so hard as scarcely to be digestible. Cheese, in most cases the casein is curdled with the hater, and a large percentage of this substance is found in all good cheeses. Still cheese is made by adding the cream of one milking to that of another, so that this cheese has double the power of the butter. This process of condensation of separated or insoluble casein will perhaps explain the neglect of beans, peas, and lentils, as articles of diet, although they contain a much larger quantity of nutritious ingredients than meat.

In conclusion, upon this subject, we present our readers with a summary of the conclusions on this subject arrived at by one of our most recent physiological writers. Dr. Carpenter, in his 'Principles of General and Comparative Physiology,' thus concludes this part of his subject:—

"The waste of the tissues, of which gelatin is the basis, may be supplied either by alburneous, proteinaceous, or gelatinous compounds, since there is no doubt that alburneous compounds are the best for the purpose. Although the reverse process cannot be performed. As gelatin does not exist in plants, it must be formed in herbivorous animals at the expense of the alburneous elements of their food; whilst in carnivorous animals it is probably derived immediately from the gelatinous compounds of the bodies on which they prey. The materials of the adipose tissue, and the olesgenous particles which seem requisite in the formative operations of the system, generally are derived in the carnivorous races from the fatty substances which the herbivorous animals may contain; whilst the herbivorous not only find the olesgenate state in their food, but also have the power of producing them by the conversion of farinaceous and saccharine matters.

"The foregoing statements are applicable to all tribes of animals 'cold-blooded' as well as 'warm-blooded.' We have now to consider the special case of the latter. In the carnivorous tribes the waste of the tissues is so great, in consequence of the restless activity which is habitual to them, that it appears to furnish a large proportion of the combustible material required for the maintenance of their proper temperature. The remainder is made up by the fat of the animals on which they feed: and it is to be observed that the amount of the heat produced in this case is not far from the colder regions of the globe than in the inhabitants of tropical countries. In the herbivorous tribes the case is different: they are for the most part much less active; and the waste of their tissues consequently takes place in a less rapid manner. It is thus that we find the herbivorous animals, having an adequate amount of combustible material, especially in cold climates. Their heat is in great part sustained by the combustion of the saccharine and olesgenous elements of their food, which are appropriated to this purpose without having ever formed part of the living tissues and the adipose matter, or at any rate in proportion to the depression of the external temperature, a greater generation of calorie being then required to keep up the heat of the body to its proper standard. Hence, cold-blooded animals can never sustain the exertion of food longer than warm-blooded, and this more especially when they are kept cool, so that they are made to live slowly, and death when at last does ensue is consequent upon the general deficiency of nutrition. On the other hand, warm-blooded animals, whose temperature is uniformly high, must always live fast, and deprivation of food is fatal to them, not only by preventing the due renovation of their tissues, but also by destroying their power of sustaining their heat. The duration of life and these circumstances depends upon the amount of fat previously stored up in the body, and upon the retardation of its expenditure by external warmth, or by the inclosure of the body in non-conducting substances; and there is evidence that if this be duly provided for, and all the other necessary precautions such as a uniform activity be practiced, the life even of a warm-blooded animal may sometimes be prolonged for many weeks without food.

"It will be gathered from the foregoing general remarks that food may be divided into two great classes—the heat-giving and the flesh-forming; and we now present a table of some of the more ordinary kinds of food, in which one or the other, or both, of these classes of substances are found mixed.

The quantity of carbon expresses the relative heat-giving power of the food. With foods containing fat the quantity of hydrogen should also be taken into consideration."
Such a table as this will be found useful in constructing dietaries for large institutions, which are very often erroneously constituted, and a large waste thereby entailed. The following table contains examples of dietaries, drawn up by Dr. Lyon Playfair, from various sources. This table accompanied an abstract of a lecture by Dr. Lyon Playfair on the Food of Man, delivered at the Royal Institution in May 1853. The following extracts from this lecture will explain some of the valuable results obtained by Dr. Playfair.

To show now, it is known that the heat which was due to the combustion of the unassailed ingredients of food, man inspires annually about 7 cwt. of oxygen, and about 1-6 of this burns some constituent and produces heat. The whole carbon in the blood would thus be burned away in about three days unless new fuel were introduced as food. The amount of food necessary depends upon the number of respirations, the rapidity of the pulsations, and the relative capacity of the lungs. Cold increases the number of respiration and heat diminishes them; and the lecturer adduces well-known cases of the necessity of residents in arctic regions, although he admitted, as an anomaly, that the inhabitants of tropical climates often show a predilection for fatty or carbo-naceous bodies. He then drew attention to the extraordinary records of animal dietaries in the Various civilized Nations, admitting that they are extreme cases even in the arctic regions, are nevertheless very surprising.

"Dr. Playfair then adduced to the second great class of food ingredients, namely, those of the same composition as flesh. Becarria in 1743 pointed to the close resemblance between these ingredients of flesh, and asked, 'Is it not true that we are composed of the same substances which serve as our nourishment?' In fact the simplicity of this view is now generally acknowledged; and albumen, gluten, casein, &c., are now recognised as flesh-formers in the same sense that any animal aliment is.

"The old mode of estimating the value of dietaries, by merely recording the number of ounces of solid food used daily or weekly, and quite irrespective of its composition, was shown to be quite erroneous; and an instance was given of an agricultural labourer in Gloucestershire, who in the year of the potato famine subsisted chiefly on flour, consuming 69 ounces weekly, which contained 269 ounces of flesh-formers. When potatoes cheaped again he returned to a potato diet, and now eats 291 ounces weekly, although his true nutrient in flesh-formers was only about 8 or 10 ounces. He shows how, further by calling attention to the six peeper dietaries formerly recommended, to the difference between the salt and fresh meat diet of the sailor, &c., all of which, relying on absolute weight alone, had in reality no relation in equivalent nutritious value.

"The soldier and sailor as illustrating healthy adult men, they consumed weekly about 35 ounces of flesh-formers, 70 to 74 ounces of carbon, the relation of the carbon in the flesh-formers to that of the heat-givers being 1-2. If one of the aged were examined with this it would be found that they consumed less flesh-formers (25-60 ounces), but rather more heat-givers (73-78 ounces); the relation of the carbon in the former to that of the latter being about 1-6. The young boy about 10 or 12 years of age consumed about 17-2 ounces as flesh-formers of the adult man; the carbon being about 85 ounces weekly, and the relations of the two carbons being nearly 1-8. The circumstances under which persons are placed influence these proportions considerably. Work-house dietaries were observed to require large amounts of fuel food to the body; while the relative amount of labour determines the greater or lesser amount of flesh-formers. Accordingly it is observed that the latter are inactive, and the former active.

"The vitamin in flesh is so important as to recommend the quantity of flesh-formers in food we may estimate approximately the rate of change in the body. Now, a man weighing 140 lbs. has about 4 lbs. of flesh in blood, 27 lbs. in his muscular substance, &c., and about 5 lbs. of vitaminous matter in the bones. The 140 lbs. would be kept in food in about eighteen weeks; or, in other words, that period might represent the time required for the change of the tissues, if all changed with equal rapidity, which however is not at all probable.

"As carbon as food is not burned in the body, part of it being excreted with the waste matter. Supposing the respiration to be 18 per minute, a man expirers about 8-69 ounces of carbon daily, the remainder of the carbon appearing as vitaminous matter.

"The substances used as food which we have called medicinal are very numerous. They include acids, volatile oils, and the vegetable alkaloids.

"The acids are eaten in fruits, such as the citric, malic, tartaric, and oxalic acids. It is possible they may be decomposed in the system, and furnish the materials of animal heat. They seem however to perform a more important part in dissolving up the mineral ingredients taken into the system as food. This seems one way in which carbonic acid is produced, the other being the action of the acids on the effervescence of waters. Acetic acid, or vinegar, acts probably in the same manner as the other acids.

"The volatile oils are added to other kinds of food, and, as condiments and spices, form a conspicuous feature in the action of the mucous membrane of the stomach.

"The use of tea, coffee, chocolate, and Paraguay tea, in infusions, constitutes a curious class of alimentary substances. To Dr. Playfair's cuisine, tea was the only article for which he gave an example, to every instance, to which the names Tea or Caffein has been given. A substance very similar, Theobromine, is found in chocolate. It is undoubtedly upon the action of these substances that the distasteful uses of these plants depend.

"The last class of this principle is Liebig suggested that the taurin found in the bile was formed from the waste tissues of the body carried into the blood; and that this taurin was necessary for the production of carbonic acid gas, or rather to get rid of the carbonic gases in the system in the form of carbonic acid gas. The taurin must be constantly formed, otherwise the heat of the body is not maintained, the carbonic matter not got rid of, and disease is engendered. If persons have not sufficient food, or if the digestive organs do not enable them to carry a sufficient quantity of nutriment to the system, the tisues of the body are consumed to form taurin. Liebig found that the latter had a composition identical with taurin, or so nearly as to render it a sufficient substitute. The same theory is applied to the combination of half the food we have been talking of as meat, to the half of the bodies we were actually preventing the waste of the body, and so maintaining health at such expense as we could by taking more solid food.

"Persons who cannot consume a sufficient quantity of food to yield the carbon necessary for generating animal heat, have recourse to tea, and find it actually a nutritious article of diet; and it is only, says Liebig, 'by such means as this that it can act as a nutritive agent.' But another theory has been given, that taurin is the condition of the composition very similar to nervous matter. Now, seeing that every operation of the mind must be attended with a loss of nervous matter, there is a necessity for a supply of that nervous matter to enable the mind to carry on its operations. A large quantity of proteinaceous matter would be
required to be supplied to form the nervous matter with proper constituents if taken in by means of meat or bread. But these alkaloids at once become a constituent of nervous matter; and this accounts for the agreeable stimulus and permanent effect on the mind produced by the use of tea and coffee, particularly by studious persons, as well as those whose nervous systems are exhausted from various causes.

In any just estimate of diet the mineral ingredients should be considered. The forms which they assume in the system are not well known, but we have a capital instance in the phosphate of lime, which, forming a part of the bones, we know must be supplied through the diet. This substance is found in the cereal grains, and perhaps one reason that man takes these grains everywhere for the substantive articles of his diet is the possession of this substance. Iron is another substance which is frequently deficient in the blood. It is naturally supplied in the food; but this failing, iron is given medicinally. Potash in combination with vegetable acids seems to have the power of preventing scurvy. Chloride of sodium is another well-known instance of the necessity of mineral ingredients in the food.

| **A few plain rules for taking food will properly conclude this article.** | | | | |
| In the first place, food should be properly cooked. Many substances which are very indigestible when in the raw state are rendered perfectly digestible by cooking. Although the stomach is capable of digesting fruits and some kinds of seeds without any exposure to heat, yet, as a general rule, the breaking down of the tissues which occurs in cooking greatly facilitates the digestion of both animal and vegetable food. But whilst that cooking is proper which enables the stomach more easily to reduce the food to the condition of chyle, there are extremes of preparation which however palatable are to be avoided. Food that is much prepared, so as to reduce it to a fluid condition, as soups, stews, and various made dishes, do not present sufficient solid matter for the healthy process of digestion to be carried on. When
the object is to prevent the stomach from doing duty such food is proper. It may also be taken occasionally with advantage as a variety in diet, but food taken long together in this form is injurious.

Much indigestible food at a time should be avoided. Many of the articles of our diet are less digestible than others and should be eaten in small quantities. It is when such substances are made the principal constituents of a meal that danger is likely to arise.

To mention only a few of the less digestible kinds of foods—Unsifted flour and bread, and biscuits, unsifted vegetables as made by modern manufacture, coffee, tea, salt, pickles, sour milk, curry, ginger, red pepper, unripe corn, apples, melons, apricots, dates, figs, many kinds of fruit, bananas, dates, lemons, oranges, garlic, sauerkraut, unripened meat, bacon, and the fat of meat, some kinds of fishes, especially the Ostreaces, crabs, lobsters, &c. Heavy meals of any one of these articles of diet, or mixtures of them, may be very injurious and produce serious attacks of indigestion, if not other diseases.

Solid food should be well masticated before it is swallowed. The teeth are organs given us on purpose to perform this function, and its accomplishment is attended also with the mixture of the saliva with the food, which seems to be an important step in the process of digestion. Although by hasty mastication persons in business hope to save their time, they should know that at least it is a loss of food, if not impairment of health. Much more is digested when it is well masticated than when it is swallowed very hastily in large masses. Food that is imperfectly masticated is digested with difficulty, and remains sometimes so long in the stomach as to produce irritation of the stomach, and remaining unacted upon it putrefies, producing pain and taint the breath.

Even where mastication is very complete it is always better to swallow slowly, as by this means every part of the food is brought more fully under the influence of the gastric acid of the stomach, by which it is prepared for absorption into the blood. Full and heavy meals should be avoided. It is better to get up off the table with an appetite than to feel that no food is required; and always digest food slowly. Food should be with propriety taken. Some systems will bear twice as much food as others, whilst there are those who require twice as much food as others. Scales and weights are not the best of tables, as some men will starve on what others will thrive. There is an instinct which, if obeyed, constantly cries "Hold, enough;" which if men would listen to would always guide them right. The feelings after eating should be those of refreshment and comfort—feelings that are not often present when too large a meal has been eaten. All food taken into the system and not wanted is likely to be in the way, and the processes adopted by nature for getting rid of the incusus are not unfrequently attended by disease and death.

Persons who habitually over-eat are frequently obliged to have recourse to medicines to correct the errors of their indulgence. Such an unnatural way of correcting the evils of an unnatural habit is itself likely to produce disease in the system.

Active bodily exertion should not be taken immediately after the principal meal. The stomach requires a supply of blood to perform its functions. If the current is diverted to other organs digestion is prevented. On this account reading at meals is an objectionable practice. The brain in this process gets the blood which the stomach requires. Long walks and hard study should both be avoided after a full meal.

Long fasting is bad. It is bad when the body is resting; it is much worse when the body is actively engaged. The stomach, like all other organs, performs its functions in virtue of the stimulus afforded it by the blood. If the blood is allowed to go a long time without a renewal of its constituents it no longer supplies the nervous system with energy to the stomach, and even other organs, flag in the performance of their duty, and as a consequence digestion is imperfectly performed. How often should man eat in the day? In the morning, at noon, and at night, is the answer given by the instincts of man.

The body can go longer without food whilst resting than when awake; hence persons may with safety go a longer number of hours between the night and morning meal than between the morning and noon, or the noon and night meals. There are no rules without exceptions in certain cases, and there are many circumstances which must modify the application of the foregoing rules, as well as in other ways regulate the taking of food.

Age is a perpetually modifying influence. The new-born infant requires the food which nature has provided for its use every hour or two. As it grows older the intervals at which it takes its food become somewhat longer; but there may be instances where children should have more eating times than adults. Grow-up people are too apt to assume that what is good for themselves is good for children; hence as great an amount of suffering is entailed on children by restrictions upon the time and amount of food as by the richness as come upon them from absolute want among the poor. The craving appetite of children is no vice of fallen human nature, but the incessant demands of an ever-wasting yet ever-growing human body. Bread and butter, or trucule, with constant consumption, is never always bad. It is rapidly growing boys and girls between the hours which adults find convenient for their meals. An evil however arising out of the healthy appetite of youth should be guarded against; it is, that while growing children are acquired of eating large quantities of food which are no longer required when growth has ceased. If the appetite is not checked by reason at this period of life, the habit of eating more than is necessary may be productive of evil results.

Other things being the same, more food is required than the adult, though not in so large a quantity. "A little and often" is a maxim that enables many aged persons to continue their influence in the world, whilst an attempt to maintain the habits of youth and middle age has cost many declinists their health and prosperity.

The mode of life influences the diet. The sedentary, the inactiv, do not consume so much muscle and nerve in their existence as the active and laborious, and accordingly require less food. The tailor ought not to eat the same as the day-labourer; and the lady all day in her drawing-room or carriage cannot expect the appetite or the enjoyment of food which is bestowed by the laws of nature on her housemaid.

Other things being the same more food is required in winter than in summer, more in cold climates than in hot ones. This arises from the greater consumption of certain parts of the food in maintaining the animal heat in order to keep off the external cold. Hence, to bring the appetite of Christmas to the Midsummer meal is to run the hazard of a surfeit; whilst the traveller who carries the eating habits of the north to countries under the line frequently perishes of fevers brought on by repulsion.

FORAMINIFERA (Foramen, fer), a group of minute Marine Animals of low organisation, consisting of a slimy transparent substance, with a single chambered, usually spiral, shell; found in non-sand and amongst marine refuse dredged up from deep water. Owing to many of their shells having a spiral form, these creatures were long thought to be homologous with the Mollusca, allied to the living Nautilus—error into which most naturalists fell until recently, when these animals became the subject of a more rigorous and searching investigation than they had previously undergone.

Though usually very minute, their elegant forms easily attracted the attention of naturalists. They were noticed by Gmelin, Planchus, and Ledermerlin, prior to the appearance of the 'Systema Naturae' of Linnaeus. In the latter work they are included amongst the Nautili, the animal, as well as that of the shell. Linnaeus associates them, being alike unknown to the Swedish naturalist. In the 12th editions are descriptions of 15 species. In 1780 Soldani, an Italian priest, published two elaborate works, abundantly illustrated, and largely devoted to the Foraminifera; the forms of Foraminifera were there divided into groups (such as Nautili, Hammonia, and Orthocerata) in the most arbitrary manner; but the works are monuments of his labour and perseverance. In 1784 Dr. Mouchet described the species under the name of 'Testacea Minuta Pariata.' The 'British Conchology' of Moutage, 1803 (and 'Supplement,' 1806), contained a still larger number of British forms, respecting the majority of
which the error of Linnaeus was still followed; but some were shown to be so different from the true Foraminifera as to render the attempt for a classification of the various portions of the shell an impossibility. M. D'Orbigny, in his book on the molluscs, figured many of the spiral forms, which he included amongst the Nautilis. In 1808 De Montfort attempted to subdivide the group into a number of separate genera, but still regarded them as Cephalopoda, in which view he was followed by Sedgwick. In 1826 the study of the Foraminifera received a fresh impulse from the labours of M. D'Orbigny, a French naturalist, who in that year presented his first memoir on the subject to the French Academy. This memoir embraced the classification of the Foraminifera, the characters of the different genera or families allied to the Cuttle-Fish; with which group of organisms D'Orbigny, like his predecessors in the study, imagined the Foraminifera to have the closest affinities. He first subdivided the class into 25 genera, and these again subdivided into a number of genera, most of them new; the various forms being thus thrown into natural groups in a way that had not previously been attempted even by De Montfort. Though D'Orbigny retained the erroneous idea of his predecessors as to the zoological relation of the Foraminifera, this error did not affect the value of his subdivisions of the class, which constituted an important step in advance of all that had been done by others. Indeed the value of his classification is shown by its retention in the zoological works of others who have written on the group which D'Orbigny published.

He distributed the species into 65 genera, introducing into the catalogue an enormous number of new forms, which he discovered in sands brought to him from various parts of the globe, and which he considered as well worth the attention of systematists. Expecting the molluscan character of these animals were sanctioned by Cuvier in an edition of the 'Animal Kingdom' published in 1828.

In 1835 M. J. Dejean presented a memoir to the 'Annales des Sciences Naturelles,' based upon an examination of the recent animals of the Foraminifera, in which he rejected the idea that they had any affinities with the Mollusca. He pointed out the fact that the animal which tenanted the calcareous shell was a mere animal slime, having no visible organs other than those of an isolated, highly organised Cephalopoda, with which they had previously been associated. He considered their true zoological position to be near the Amoeba, commonly known as the Protists Animals, and to those constitute part of a larger group, to which he assigned the name of Ethopoda.

In 1834 and 1839 Professor Ehrenberg presented two memoirs to the Academy of Berlin, in which he advocated the opinion that the Foraminifera were polype-bearing animals, allied to the Polypidae, in which view he followed the suggestion of Cuvier, by which they formed the first order, Polyplaxina. He also assigned to them internal organs which no other observers have been able to discover: but notwithstanding these errors he did good service by the discovery that the genus Ammonites bore no relationship to the Foraminifera, which were the nearest relatives of the shellless molluscs of the Acanthophora, which by their gradual accumulation had thus produced widely-extended masses of calcareous strata, many hundreds of feet in thickness. The existence of numerous fossil Foraminifera in the chalk had been demonstrated by Mr. Lonsdale in 1835; and still later, the rich harvest of beautiful forms to be obtained from these Cretaceous strata was further demonstrated by M. D'Orbigny in his monograph "On the Foraminifera of the White Chalk." In 1845 Professor Williamson published a memoir in the 'Transactions of the Literary and Philosophical Society of Manchester,' in which he further demonstrated the absence of any real resemblance between the Foraminifera and the Polypidae, and the component nature of any resemblance to the former in an inferior portion of the zoological scale. At first he adopted the idea of his own, but in a subsequent memoir (1848), he came to the conclusion that they were not polype-bearing, but that they approximated to the Brachiopoda. In this matter, and had been asserted by M. Dejean, to the Amoebra or the other: their true position in any linear arrangement being immediately above the former of these classes of objects. In another memoir, read in 1861, describing the complicated structure of some forms of the Foraminifera, and the zoological affinities of the animal existing at the structure of the shell of the Ordovican Tabulata, and especially at the large orifices which communicate between its various cavities, we cannot fail to observe that it is a reticulated calcareous skeleton, whose propontiative relation to the size of the soft animal has suffered but little from that of the siliceo-keratoine network of many sponges to the slimy substance with which they are invested. The attempt for a satisfactory classification of the various portions of the shell the Foraminifera. The genus Foraminifera, however, raise each portion to the rank of an individual animal, even in the limited sense in which we should admit such a distinction in the polyplas of a Sertularia or of a Gorgonia, appears to me wholly inadmissible. If the soft structures of the Foraminifera are Lichinaria, and the hard shelled, we British Foraminifera, and I have very little doubt that such will prove to be the case, the whole animal will be very little raised above the Polyplaxina, only possessing a symmetrical calcareous skeleton, which is at once both external and internal characteristic ('Transactions of the Geological Society of London.')

In 1848 M. D'Orbigny published his work 'On the Fossil Foraminifera of the Tertiary Basin of Vienna,' in which he developed the idea that they were the remains of true Cephalopoda, the introduction, the group into the classification of the Foraminifera, the comparison demonstrates that they cannot be arranged in any of the known Zoological Classes. Much less complex than the Echinodermata or the Polyplaxina as to their internal organisation, they are more nearly related to the Polyplaxina, to the order of locomotion of the former, and are by their isolated, non-aggregated, free existence, more advanced in the scale than the latter. This individual existence of the Foraminifera, the liberty which they enjoy, and their mode of locomotion, are characters which deserve to be taken into account. Although less complex than many Polyplaxina, they have not a common aggregate life. A multitude does not unite to form a regular body as amongst the Polyplaxina. They are locomotive, which the others are not, and their mode of locomotion, the regularity of the testaceous envelope of their segments places them far above the Polyplaxina. On the other hand, much less perfect than the Echinodermata, they are very inferior to them in all respects. We believe also that, because of the radiation of their offspring, the position of the Foraminifera is in the interval (embranchment) of the radiating animals of Cuvier, between the Echinodermata and the Polyplaxina, as an altogether independent class. ('Sur les Foraminifères Fossiles du Bassin Tertiaire d'Austria,' p. 230.)

There can be no doubt of their great inferiority to the Echinodermata, which possess a distinct alimentary canal, a nervous circulatory and sexual system; and communicating with the definitive division of these animals. The discovery of a distinct reproduction by ova, through the agency of medusoid forms, we must conclude that these latter are equally removed from the structureless animals of the Foraminifera. In the preceding argument M. D'Orbigny forgets that the freedom, isolation, and independence, upon which he lays so much stress, are the characteristics of the fixed compound Polyplaxina, in their embryonic or larval states. Consequently this feature, which in the Foraminifera is normal and permanent, betokens inferiority rather than superiority to the Polyplaxina, in which aggregation and fixation indicate maturity and a higher development. The argument drawn from their symmetry is of no value. Nothing can be more symmetrical than many of the sponge spicula, and in the vegetable kingdom, the symmetrical plants (Dennidos) are amongst the lowest forms.

An additional memoir by Professor Williamson, in 1851 ('Quarterly Journal of Microscopical Science,' vol. 1.), afforded other and still more striking evidence of the proboscis correspondence of the Foraminifera. He was not published by the structure of a species of Funainasina, and especially showed that the new growth which added to the thickness of the shell were all applied to its exterior and not to its interior, apparently indicating that the gelatinous animal shell, or of retreating to its interior at will, reminding us of the movements of the gelatinous envelope in some of the less highly organised Funiform Corals. (R. Jones, 'Animal Kingdom,' p. 19.) In 1843 Dr. Carpenter laid before the Geological Society of London an elaborate memoir

Digitalized by Google
on the structure of some interesting fossil forms belonging to
the genera Orbitolina and Nummulina, which with the
publication of M. D'Orbigny on the Foraminifera of Cuba,
constitute the chief additional works that have appeared on
this subject.

The following is the latest classification of the Foramina-
fera adopted by M. D'Orbigny, and though marked by some
imperfections, it is the best that has been hitherto published.
The five principal divisions are chiefly based on the varia-
tions in the arrangement of the success-
ively added segments.

Order 1. Monostega.—Animal consisting of a single seg-
ment. Shell composed of a single chamber. Genera: Ov-
usplina, D'Orbigny; Orbitolina, D'Orbigny; Calina,
D'Orbigny.

Order 2. Stichostega.—Animal consisting of segments ar-
ranged in a single line. Shell composed of chambers
superimposed linearly on a single straight or curved
axis. No spiral growths —

Glandulina, D'Orbigny.

Nodosaria, Lamarck.

Orbigerina, D'Orbigny.

Dentalina, D'Orbigny.

Dorloculina, Defrance.

Lingulina, D'Orbigny.

Order 3. Holocystea.—Animal consisting of segments ar-
ranged in a spiral. Chambers piled up or superimposed
on one axis, forming a spiral volute —

Cristallaria, D'Orbigny.

Mangiulina, D'Orbigny.

Robulina, D'Orbigny.

Rimulina, D'Orbigny.

Pavonina, D'Orbigny.

Conulina, D'Orbigny.

Middletonina, D'Orbigny.

Marginulina, D'Orbigny.

Vulvulina, D'Orbigny.

Lingulina, D'Orbigny.

Order 4. Entomotega.—Animal composed of alternating
segments forming a spiral. Chambers piled up or
superimposed upon two alternating axes, forming a
spiral —

Hispidulina, D'Orbigny.

Astyloculina, D'Orbigny.

Orthocerina, D'Orbigny.

Adamina, D'Orbigny.

Ampitphila, D'Orbigny.

Order 5. Multistega.—Animal composed of alternately
arranged segments without forming a spiral. Chambers
disposed alternately along two or three distinct axes,
not forming a spiral —

Dimorphina, D'Orbigny.

Gastrulina, D'Orbigny.

Fusulina, D'Orbigny.

Textularina, Defrance.

Softulina, D'Orbigny.

Planulina, D'Orbigny.

Planongulina, D'Orbigny.

Astyloculina, D'Orbigny.

Order 6. Agathostega.—Animal composed of segments
wound round an axis. Chambers wound round a com-
mon axis, each one investing half the entire circumference —

Uniloculina, D'Orbigny.

Biloculina, D'Orbigny.

Orthoculina, D'Orbigny.

Faculina, D'Orbigny.

Spherulina, D'Orbigny.

Fusulina, D'Orbigny.

Sphaerulina, D'Orbigny.

Spiralina, D'Orbigny.

Frondiculina, D'Orbigny.

Triloculina, D'Orbigny.

The simplest type of the Foraminifera (Monostega), pre-

cents but a single segment, and is illustrated by the Orbit dealing

with a small spiral shell with a lateral aperture, the interior of which has been occupied by

the living jelly to which the shell owes its existence. The

beautiful symmetrical Logenes, or Flank Animals (fig. 5),

the British species of which have been figured by Professor

Lamarck in the 'Annales of Nat. Hist.' also belong to

this type.

In the order Stichostega, as for example the Nodosaria,
Dentalina (fig. 3), the shell advances beyond the simple

type of the Monostega by a process of linear budding. The
first cell is usually spherical, as in Orbitolina, but through

the orifice in this primary cell there protrudes as a growth from

the contained animal segment, a second segment, usually

a little larger than the first, which speedily increases itself in a

shell covering. This new growth is successively followed by

others developed in the same way, until the organism

attains to its maturity, when it exhibits a series of cells

arranged end to end in a straight or but slightly curved line.

In the Holocystea, a large and conspicuous group, the

gemmation takes place with a spiral bias, producing the

nautiloid form of shell which misled the earlier microscopists.

Sometimes all the convolutions are visible. (Operculina,
fig. 4.) In others the outer convolution embraces those

previously formed, and conceals them. (Orbitolina, fig. 6.)

In a third type all the spiral convolutions are visible on one

truncated half of the shell, whilst they are embracing on the

others (Panulina, fig. 6), thus combining the other two
types. Some genera, like the Stichostega and Holocystea

orders, develop on the plan of the latter, up to a certain

stage of their growth, when the arrangement of the cells

ceases to be spiral and becomes straight (Operculina, fig. 7),
as in the Nodosaria. The orifices penetrating the septa and

connecting the contiguous segments are sometimes single, and

at others numerous.

1. Orbitolina undulata. 2. Logonia affinis, veg. porcellan. 3. Dentalina

Lagenaria; Chalk. 4. Operculina. 5. Orbitolina Lagenaria; Chalk. 6. Pan-

ulina. 7. Operculina.
primary central one, as the thread is around a ball of worsted. (Orthocerasculum, Triloculatum.)

In the great majority of the species the interior of each chamber is simple and undivided, but there are some forms, especially amongst the Helicocystidae, in which the newer and more external chambers are subdivided either by transverse pillars or by complete partitions perforated by one or more apertures, through which prolongations of the gelatinous substance unite the various segments of the soft animal. (Orthocera, fig. 11.) Ordinarily but one such chain of communications exist (animal of Rosalina, fig. 12); but in the cases just referred to, there is a great increase in the number of such orifices, so that the septa become completely cribiform.

The distribution of these apertures affects the gommatum or mode of growth, since it is through them that the new segments are successively formed, the gelatinous substance being extended by a process of budding or sprouting. An increase in the number of such orifices is most common where the consecutive segments present a rapid increase in their size. In the genus Orthocera, this growth is sometimes so remarkable that the new segments soon form concentric circles, embracing all those previously formed. (Orthocera complanata, fig. 11.) In such examples the connecting apertures are distributed round the entire periphery, and gommatum most probably takes place simultaneously through them all; so that the soft animal, if decalcified by an acid, would present a succession of rings, inclosing one another, and connected together by transverse radiating bars.

The memoirs of Professor Williamson have shown that the shell inclosing each new segment is at first very thin; but as additional calcareous chambers are formed, each such addition not only increases the new gommatum of the soft animal, but extends over all the exterior of the former shell. The exact way in which this is accomplished is doubtful; but it is probable that the soft animal has the power of diffusing itself over the shell, and depositing upon its surface additional layers of calcareous substance. Through these formations the delicate processes of the soft animal, termed pseudopodia, are protruded. The exact use of these, whether for tactile, probosidea, and locomotive purposes, or for the inception of new chambers, is not understood; but experiments have been made, which, though not very satisfactory, are sufficient to show that they are capable of accomplishing the process both in a single and double form. The Foraminaria in the calcareous shell present various appearances. Sometimes they are large and conspicuous (Rosalina globularis, fig. 13); at others they are so small that their presence is only to be demonstrated by means of high magnifying powers. Through these forms some of the processes of the soft animal, termed pseudopodia, are protruded. The exact use of these, whether for tactile, probosidea, and locomotive purposes, or for the inception of new chambers, is not understood; but experiments have been made, which, though not very satisfactory, are sufficient to show that they are capable of accomplishing the process both in a single and double form.

The foraminaria in the calcareous shell present various appearances. Sometimes they are large and conspicuous (Rosalina globularis, fig. 13); at others they are so small that their presence is only to be demonstrated by means of high magnifying powers. Through these forms some of the processes of the soft animal, termed pseudopodia, are protruded. The exact use of these, whether for tactile, probosidea, and locomotive purposes, or for the inception of new chambers, is not understood; but experiments have been made, which, though not very satisfactory, are sufficient to show that they are capable of accomplishing the process both in a single and double form.

Professor Williamson has also demonstrated the existence in several species of a curious system of intersepas and transverse strata arranged uniformly along the walls of the shell. (Rosalina, fig. 14.) These are especially obvious in the genera Pseudoceras, Ophioceras, and Amphistegina. The tubes open at the exterior of the shell, especially at the periphery of the margings, either by a few large or by numerous small apertures. These canals are probably designed to admit water to the interior segments of the animal, with which they communicate through the minute foramaria. In some cases the pseudopodia are protruded through such of these canals as are situated in the umbilical region; but these appear to be exceptional instances.

The relations of the Foraminaria to Palaeontology render them interesting objects to the geologist. Many of the more recent calcareous shells chiefly owe their origin to the accumulation, through successive ages, of these minute stones. The white chalk rocks are mainly composed of them; vast ranges of Tertiary strata present the same characteristic features; and though the older limestone, having been so altered by pressure and chemical agencies that their origin is less clear, there are many indications that they have primarily resembled the rocks of more recent age—an inference that is rendered probable by the great extent to which sediments now accumulating in the bottom of the sea are charged with these little organisms, and in some cases entirely composed of them.

The fossil Foraminaria are chiefly distinguishable from recent ones in the greater prevalence of specimens of comparatively small size. Though one recent species is sometimes brought from Borneo by Sir E. Belcher measuring more than two inches in diameter, the living forms usually range from the 4th to the 44th of an inch. But the Tertiary strata of the earth abound in examples of the fossil genus Nummulite (Nummulina, fig. 18), so called from their resemblance to coins, which vary from 4th of an inch to the size of half a crown. These are often so abundant as to form mountain masses, extending through the Alps, Northern Italy, Greece, Syria, Egypt, and North-east India. The Mokkadam Mountains in Egypt, where the stones used in building the pyramids was obtained, chiefly consist of these Nummulites which are known to the natives by the name of Pharaoh's Glasses.

The structure of the Nummulites has been investigated by Moser, Jolles and Leymus, and especially by Dr. Carpenter, whilst the specific forms have been studied by M. D'Arocian. The genus belongs to the group of the order Helicocystidae, in which the outer convolutions completely embrace the earlier-formed ones; hence it is only by making microscopic sections or thin slices, that their structure can be fully seen. When such a section is carried horizontally through the centre of the shell the segments present a spiral arrangement; they as well as the aperture being large enough for their small size and consequent great number. In other respects they present few or no essential differences distinguishing them from more recent forms. A still more curious genus, known by the name of Orthoceras, occurs in America, Switzerland, and India; in this latter country it is represented by a species which comprises, with its numerous varieties, a considerable number of the shells which are more perfectly preserved than any other. The shells of Dr. Carpenter have revealed a remarkable structure in this
For the American Educator, see Foraminifera, Forssell, S. I.

Forssell, EDWARD, a celebrated naturalist. He was born in 1815 in the Isle of Man, where his father was a banker. Without any one to direct his taste, he became a naturalist while yet a child. Nothing delighted him so much as to pick up the productions of nature, and add them to his collection. He could read. By the time he was seven years of age he had collected a small museum. His first efforts at naming these objects were made through Turton's 'Translation of the Systems of Naturalists.' Whilst yet a hoy of twelve, he read the 'History of British Fossils,' and by this attempt at original work was the production of a 'manual of British Natural History,' which, although it was never published, was the repository of many of his notes even to the close of his life. His habit of drawing the natural history objects which interested him, led him to think of painting as a profession, and with this object in view he studied for some time in the studio of the late Mr. Saxe in Charlotte-street, London. This profession did not however comply with his restless desire to study natural facts of natural history. He entered the University of Edinburgh with the object of studying medicine. Here under the teaching of Professors Jameson and Graham he first became acquainted with the true principles of natural science, and the views and principles of one of his assistant lecturers himself becoming himself an observer and adding to the already accumulated stores of natural history facts. It was with this feeling that he started with a fellow-student on an excursion into Norway, where he made numerous observations on the rocks, plants, and mollusca of the country, and afterward published the result of his observations in a paper in the 'Magazine of Natural History,' entitled 'Notes of a Natural History Tour in Norway.'

At the very period of his natural history career he had established the importance of the dredge as an instrument of his research, and in his hands this simple instrument became as powerful a means of research as the telescope to the astronomer. With it he swept the bottom of the ocean, measured its depths by the character of its inhabitants, and discovered a law for the distribution of marine plants and animals in depth, as strict as the law which regulated their distribution on the altitude of mountains. His early papers, entitled 'Records of the British Species of Mollusca,' were published in eight volumes of the 'Journal of the Linnean Society,' and five volumes of the 'Magazine of Natural History.' Much of his student time was spent upon the sea in the neighbourhood of Edinburgh, and scarcely ever did he make a dredging excursion, so new was the operation to the naturalist of the time. The species were numerous, and increasing collection of natural objects. His attention was not at all however exclusively confined to marine zoology. Plants were always favourite objects, and no student enjoyed more or profited more largely by the botanical excursions of the late Professor Graham. This habit of excursions he had cultivated a most important element in botanic study, at once invigorating the body, and giving the student a knowledge of the relation of plants to other objects which they could not otherwise obtain. Whilst he held the chair of botany at King's College, London, he never neglected periodical excursions with his students. He was mainly instrumental in 1836 in establishing the Botanical Society of Edinburgh, of which he became the foreign secretary. In 1837 he visited Paris, attended the lectures of the Professor there, and worked in the museum and collections in the Jardin des Plantes. In the same year he visited Algiers and the coasts of the Mediterranean. In 1836 he published an account of the 'Mollusca of the Isle of Man,' and in 1839 papers on the 'Land and Freshwater Mollusca of Algiers,' and on the 'Distribution of the Pulmonifera of Europe.' In these researches he was laying the foundation for the enlarged views, which he afterwards put forth, with regard to the distribution of animals and species of animal and plants in time and space.

His papers from this time became very numerous. The materials he accumulated in his various excursions were truly astonishing. He lived to publish but a comparatively small portion of them.

In 1841 he published a 'History of British Star-Fishes,' containing accounts of several new species, with charming descriptions of the habits of these animals, and incidents connected with them. He says that his own pencil was worthy of a disciple of Bewick. In this year he accepted the appointment of naturalist to H.M.S. Beagle, commanded by Captain Graves, who was commissioned to bring from Lybia the mussels discovered by Sir Charles Fellows. The shells and other objects were brought by him, and those resources of a ship of war were placed at the disposal of a naturalist. The result of this voyage was the discovery of the great law, that among marine animals zones of depth correspond to the latitudes of the earth. On his return, the meeting of the British Association held at Cork in 1843. The detailed results of this voyage were never given to the world, and Forbes always looked forward to the day when a little leisure would permit him to publish in detail his observations. He had a great deal of patience to work on, in view of the disgrace of his country, no position was provided for him in which the necessary leisure could be found, till it was too late.

Other results came out of his Lybian excursions. In connection with Lieutenant, now Captain, Spratt, he published his travels in Lybia, with numerous illustrations made from his own drawings, and notes on the natural history of the Xegam.

In 1845 he was in Lybia that he contrived the same form of rebuttal football which killed one of his companions, the Rev. Mr. Daniel, and from the effects of which he suffered to the day of his health. While away in the Xegam, he was appointed to the Professorship of Botany in King's College, London, vacated by the death of Mr. David Don. Although he had resolved on a visit to Egypt and a dredging excursion to the Red Sea, the offer of a chair in London was too much in accordance with his tastes to refuse. He immediately gave up the medical profession, and became a naturalist for the rest of his life. He gave his first lecture in May 1844, and in the same year he was appointed assistant secretary to the Zoological Society. Both situations contributed to the development of his genius, which with the aid of more profound researches was able to systematise his knowledge, and develop his power of communicating its results, the secretariatship afforded him a means of extending his acquaintance with fossils, and the relations of extinct with recent forms of both animals and plants. These offices however preceded one more important still, that of palaeontologist to the Geological Society of Great Britain. When the Museum of Economic Geology was removed to Jermy-street, and the School of Mines founded, he was made a member of the Committee of Management, which by these appointments from publishing all he had already stored up, he added here fresh stores to his stock of knowledge; and numerous memoirs and papers in the Natural History Journals, the Proceedings of the Zoological Society, and various other geological publications, contributed to the great observing powers and unwearied industry. 'One of the most important of these papers is entitled 'On the connection between the distribution of the existing Fauna and Flora of the British Isles, and the geological changes which have affected their area.' This paper attempts to explain the distribution of the plants and animals of the British Islands, on the hypothesis that they were all diffused from a common centre, and that consequently they must have been disseminated when these islands were contiguous with those countries where the identical species are found. He then brings forward geological evidence to support his assertions, and even goes so far as to point out the fact, that at one time, and that recently, dry ground existed between the south-western portions of the British Islands and America.

In 1854 Professor Forbes was elected president of the Geological Society. In the same year he accepted the chair of Natural History in the University of Edinburgh. He was president of the geological section of the British Association which met at Liverpool in September. He died on the 16th of November in the same year. The Edinburgh chair was the object of his highest ambition. The increasing years of Professor Jameson rendered it not improbable even when he himself was master of the chair that he might one day be able to step. He commenced the duties of his new position with his usual ardour, laid down a course of action which would have required years of development, but he had barely time to deliver a preliminary summer course before he was seized with a disease of the kidneys which proved fatal in a few days.
Besides the works to which reference is made above, he was the associate of Mr. Hanley in a great work on the "History of British Mollusca," which was published in parts, and completed in 1863. This work is one of the most complete and exhaustive on the subject of our native Mollusca, and all the descriptions were written by Forbes. He contributed several valuable papers and maps on the distribution of animals and plants to the last edition of Johnstone's "Physic, Surgery, and Natural History," and also to the "Literary Gazette." His papers were collected together in "Forbes's Literary Papers" by the late Edward Forbes. The third volume of the 'Bibliographia Geolotica et Zoologia' of Agassiz and Strickland, published by the Ray Society in 1860, contains a list of eighty-nine papers and works supplied by the author himself, and arranged in chronological order. His contributions to natural history science were perhaps more numerous during the last four years of his life than during any former period of the same length. Few men have labored more assiduously in the path of natural science, produced a greater impression on the current thought of those who cultivated the same branches of knowledge as himself; and the time has not yet arrived when a clear estimate can be made of the influence he has exerted on the time in which he lived.

FORDINGBRIDGE. [Hamwicks.] FORESTALLING. This offence, long obsolete, has at length, with others of the same character, ceased to exist.

(7 & 8 Viet. c. 94.) FORSYTH, C. W. SEPT. NOT. [MYRTOTIS, S. L.] FORMICA, a genus of insects belonging to the family Formicidae. It is distinguished by having the foot-stalk of the abdomen composed of a single joint, the mandibles triangular, and dentilicate at the edge. The females are destitute of a sting. This genus contains about two dozen British species, the largest of which is the Hill-Ant or Horse-Ant, F. rufa. The nesters in this species are about one-third of an inch long, of a black colour, with the thorax, abdominal scale, and a lateral row of hairs on the hindmost joint in the open ground, in woods, &c., amassing together large quantities of sticks, straws, &c. For a description of these nests see Ant.

F. sanguinea is of a blood-red colour, with the eyes and abdomen black, and the wings dusky at the base. The neuter is similarly coloured, except that the head is darker. The male is black, with red legs. This species abounds in wood, and is one of those which steals the young of other species, reversing them to perform the duties of the nest. Two of the species are parasitic in the nest of the C. cucullata and F. fusca, both of which are inhabitants of this country. The latter species is of a shining black colour, with a slight ashy tinge; its form is rather long, and it is nearly smooth; the three anterior joints of the foot-stalk are of a red colour, as are also the legs; the abdominal scale is large and triangular; and the ocelli are distinct. It establishes its nest under stones, moss, &c., and at the foot of trees, the nest being entirely under ground. Among the exotic species of this genus are to be found many which are extremely injurious or annoying in their habits. Of these the Sugar-Ant of the West Indies is perhaps the most extensively prejudicial. F. saccharivora, as it is called, establishes its nest at the root of sugar-canes, limonies, and similar plants, and the ceaseless gnawing of the trees are either blown down by the violent gales, or so completely deprived of nourishment as the roots that they soon die. Some years ago the injuries committed by this insect were so great that a reward of 20,000l. was offered by the planters to any one who should discover an effectual mode of destroying them, yet nothing could be found to stay their ravages. The aid of fire was even resorted to in vain; the insects rushed into the flames in such myriads as to extinguish it. Heavy torrents of rain at last effected their destruction.

F. indentata, another exotic species, is described by Colonel Sykes as being an extraordinary instance of the operations of instinct in the case of insects. "I have," says he, "observed insects for sweet substances is very great, and their attacks on such things were resisted in every possible manner, yet although the table, on which the confectionary and sweets were, was placed with its legs in water and removed a short distance from the wall, they succeeded in reaching them, to the great astonishment of all, until the mode of access was discovered. Colonel Sykes says, "I observed an ant upon the wall about a foot above the level of the sweets; it fell, and instead of passing between the wall and the table, and alighting upon the ground it fell upon the table." Others followed its example with similar success; and it was no longer a matter for doubt as to how they continued to swarm in such numbers about their favourite food, however carefully guarded generally was the table." FORMICIDÆ, an extensive family of Hymenopterous insects, belonging to the section Aculeata, and to the sub-section Heterogyna of Latreille, comprising the Linnean genera Formicus, Apis, and the numerous tribes of Ant. The family is distinguished by the single sting, which is composed of a single joint, the male of seven. The females and nesters are furnished with a single sting, of one species. Those species which have stings emit an irritating fluid into the wounds which they make, while the stingless species discharge a red transparent fluid on to the skin, causing painful irritation.

The various genera of this family, according to Latreille, are, 
— Formica, Polyergus, Ponera, Myrmica, and Atta
This last genus differs from Myrmica only in having very short palpi; the head of the workers is generally very thick, A. eclecta, A. pergandiana, and A. aurata of the West Indies.

FORMYE. [CHEMISTRY, S. D.] FORRES. [ELGINSHIRE.] FORSTER, FRANK, civil engineer, was born in the year 1800, near Chester, and at an early age was put to learn the business of a collier, working in Westmoreland. After some years, he was intrusted with the management of mining works near Swarms and was afterwards similarly engaged in Lancashire. Whilst thus occupied, about the year 1820, he became acquainted with Mr. Robert Stephenson, under whom he was ultimately employed in the superintendence of some of the most difficult works on the London and Birmingham railway, inclusive of the Kidley Tunnel and the Blists Hill Cuttings, and somewhat later he was resident engineer to the London and Greenwich Railway. He has been associated with some of the most extensive works from near Conway to Holyhead, including the masonry of the Britannia Bridge, and difficult works in sea-walls and tunnels along the line. On the formation of the Metropolitan Board of Works, Mr. Forster was appointed chief engineer, and was instructed to furnish a general report on the London sewerage, for which many plans had been sent in to an invitation some time previously. He very soon suffered from the effects of the arduous duties thrown upon him, and which were rendered more difficult by numerous conflicting opinions and interests. He himself was freely unambiverted upon by the press, and he was at length compelled to resign his appointment, and died suddenly a few weeks afterwards, on the 15th of April 1855, in his fifty-second year. His reports and plans, so well calculated to the service of the country, were destroyed by the destruction of the London reman, and are understood to have formed the basis of the schemes now under consideration, and in which a partial commencement of work has been made.

FORTOUL, HIPPOLYTE, late Minister of Public Instruction in France, was born in 1811. He commenced active life as a literary man by contributions to the 'National,' 'L'Artiste,' and other periodicals. In the earlier part of his career he professed republicanism and St. Simonism, and was befriended by these great philosophers, who published a biography. He was a contributor to the 'Revue de Paris,' and was an unsuccessful competitor for the editorship of the 'Revue des Deux Mondes.' Mean time, by his laborious pen, he won every emanation of European honors. He was made Professor of Literature in the University of Toulouse, where he distinguished himself as a lecturer, and was afterwards rewarded for his services by being appointed Dean of the Faculty of Art. He was also admitted into the French Academy in the section of Sciences and Arts.
LETTERS.

After the revolution of 1848 he was elected a member of the French National Assembly, in which he spoke frequently, and obtained the favour of the Prince President. In January 1849 he ascended to the Eiffel Tower, and on the 1st October 1849, he was one of the six ministers who signed the decree for the confiscation of the estates of the House of Orleans. He was then in a situation of great financial difficulty and energy with which he carried out the imperial system of restriction of the press. He had gone to Ems for the benefit of his health, when he died suddenly as he was conversing with his colleague M. Magnes, on the 7th February 1849. His death occurred on the 9th February, was buried at the public expense, with the firing of guns, processions, and other honours, on the 12th of July, in the church of St. Thomas d'Aquin, Paris.

FOULSHAM. [Norfolk.]

FOXTAIL-GRASS. [Alopecurus.]

France. The 66 departments into which France is divided are subdivided into 2,169 arrondissements, 3047 cantons, and 36,835 communes, which, except that they have a corporate form of government, do not generally differ much in extent from parishes. Each department is administered by a prefect; each arrondissement by a sub-prefect; and each commune by a mayor (maire). In some departments there are also several officers connected with the arrangement and receipt of taxes, an engineer of roads and bridges, a military sub-intendant, and a company of gendarmerie. In the chief towns of each department, courts of justice are held; in each arrondissement, its tribunal of first instance, and each canton a judge of the peace. The more important departmental capitals are seats of high courts of justice and appeal, and head quarters of Military Divisions. In the following table the area and population of each of the 66 departments is given as returned in the official census of 1851.
According to the census of 1851, the population of France was divided into—Roman Catholics, 34,931,032; Réformés, 260,507; Lutherans, 280,507; Jews, 17,826; Methodists, 6,148; and miscellaneous religions, 26,383. Of the rest the religion was unknown.

The population of France at the commencement of the 18th century was about 13,669,930, exclusive of Corsica and part of Lorraine, which were not then united to France. In the year 1783 the population had increased to 21,769,163, inclusive of Corsica and the whole of Lorraine. In 1784 it had further increased to 24,800,000.

The population according to the different census returns of the present century, has been stated to be as follows:

<table>
<thead>
<tr>
<th>Year</th>
<th>Population</th>
</tr>
</thead>
<tbody>
<tr>
<td>1801</td>
<td>28,540,583</td>
</tr>
<tr>
<td>1811</td>
<td>31,491,675</td>
</tr>
<tr>
<td>1831</td>
<td>35,781,628</td>
</tr>
</tbody>
</table>

The population of the French colonies in 1851 was as follows:

<table>
<thead>
<tr>
<th>Colony</th>
<th>Population</th>
</tr>
</thead>
<tbody>
<tr>
<td>Algeria</td>
<td>2,600,363</td>
</tr>
<tr>
<td>Senegal and Dependencies (1857)</td>
<td>29,863</td>
</tr>
<tr>
<td>Sénégal</td>
<td>29,683</td>
</tr>
<tr>
<td>Guadeloupe, &amp;c.</td>
<td>128,701</td>
</tr>
<tr>
<td>Martinique</td>
<td>128,910</td>
</tr>
</tbody>
</table>

According to the budget of 1858, the total receipts of the public revenue of France amounted to 1,717,116,190 francs (about 68,686,000L), the expenditure to 1,727,116,171 francs, the expenditure thus exceeding the income by 19,006,881 francs.

In 1856, the entire army of France amounted to 577,686 men, of whom 310,347 were in France, 64,335 in Africa, 107,697 not then returned from the Russian war in the East, and 5367 in Italy.

In 1867, the total number of vessels comprising the navy of France amounted to 325, of which there were 10 of 130 guns, 10 of 100 guns, 15 of 90 guns, 5 of 80 guns, 17 of 60 guns, 17 of 50 guns, 10 of 40 guns, &c.

The constitutional monarchy and representative government which had prevailed in France under King Louis Philippe, the head of the younger branch of the Bourbons, were abolished by the republican revolution of 1848. A republic in form, governed by a president and a national assembly, the members of which were selected by ballot, by a suffrage all but universal, succeeded.

On December 2, 1851, Prince Louis Napoleon Bonaparte, President of the Republic, issued a decree dissolving the Legislative Body, establishing universal suffrage (the assembly had been called with restricted liberties), and establishing a plebiscite, which was to be a president for ten years, and a second chamber, or senate. On the 20th and 21st of December, the French people, by 7,439,216 affirmative votes against 640,737 negative ones, adopted a 'plebiscite,' or decree of the people, maintaining the authority of Louis Napoleon Bonaparte, and giving him the power necessary for establishing a constitution on the bases proposed in the above proclamation. The power thus conferred upon the President resulted in the important state paper dated January 18, 1852, which, contains the constitution under which France has since been governed.

According to this proclamation the President, while he retained that title, assumed more than royal authority. He is responsible to the people alone who had elected him, and not to a national assembly; the command of the land and sea forces, the exclusive initiation of new laws, the right to declare the state of siege, were among his leading attributes. A Senate was appointed, whose number was not to exceed 150, the members to be named for life by the President, who may also give them names. A lower chamber, called the Legislative Body, consists of 361 members, one for every 35,000 electors, and chosen for ten years by universal suffrage, but without the ballot. The sittings of both chambers are to be private, and monthly reports only of the proceedings to be published. No member of either chamber has the power to originate any law; if amendments are adopted they must be sent to the council of state, and cannot be discussed if not also adopted by this body. The President convokes, adjourns, prorogues, and dissolves the Legislative Body. In case of a dissolution a new one is to be convoked within six months. The session of the chambers to last three months.

A council of state, composed of 40 or 50 salaried members, nominated and presided over by the President, decides the projects of all laws. The Senate is not to be transformed into a court of justice. For crimes against the chief of the state and the public safety a high court (as above explained) is appointed. Ministers cannot be members of the legislature. Petitions may be addressed to the Senate, but not to the Legislative Body. The mayors of commune's are appointed by the executive.

In this draught of the constitution the name of Republic was retained, and the title of President; but on December 3, 1852, in accordance with a decree of the legislature dated November 7, 1852, and a plebiscite carried by 7,836,509 votes against 264,401, the name of the government was changed, the Empire was re-established, and Louis Napoleon Bonaparte became Emperor of the French. The successor of the Emperor Napoleon III., the throne being hereditary to his legitimate male descendants, failing which, the succession rests in Prince Jerome Napoleon Bonaparte and his direct legitimate
descendants in the male line by order of primogeniture.

Since the establishment of the Empire some modifications have been made.

FRANKLIN, REAR-ADMIRAL SIR JOHN, was born in 1766 at Spilsby in Lincolnshire. His ancestors were substantial yeomen, and his father inherited an estate in that county, which though small was sufficient to give him local rank as a landlord. Unhappily, however, the property was so embarrassed that he was obliged to sell it, and he became entirely dependent on his commercial profits for the maintenance of his family, in which situation, of which he was besides the subject of this memoir, attained considerable rank and reputation. One, Sir Williamson Franklin, became judge at Madras; and another, Major James Franklin of the Bengal service, was highly distinguished for his scientific acquirements, which procured him the fellowship of the Royal Society.

John, the youngest son, early evinced a great predilection for a sea-life. There is a story told of him which seems to rest on more than mere tradtional evidence. When a school-boy at Louth in Lincolnshire, he availed himself of a holiday to visit to the coast, a distance of twelve miles, in order to see the ocean, on which he gazed with wonder and delight for many hours. His father, who was extremely desirous of affording his son the facility of obtaining a@ sea, procured for him a commission in the Royal Navy, that of a sailer, conceived that by sending him in a small merchant ship to Lisbon, the discomfits of the voyage would effectually cure the lad of his love for the sea, but it had the opposite effect; and accordingly paying him off it was bent on a sea life. He was accordingly engaged as midshipman on board the Polyphemus at the age of fourteen, and in that ship he sailed the celebrated battle of Copenhagen, from which he escaped without a wound, whilst a brother midshipman of his fell.

He next joined the Investigator, under the command of Captain Flinders, his cousin by marriage, with whom he sailed on a voyage of discovery to the coasts of Australia. During this expedition, which combined investigations into natural history with geographical discovery, young Fra@ hick had abundant opportunities—which were not neglected—of acquiring much valuable knowledge. Besides sound practical seamanship he learned the more theoretical and difficult branches of nautical surveying, and was always one of the midshipmen selected to attend the Captain whenever he made excursions in boats, or visited the shore for scientific purposes. After some time the Investigator being unfit for further service, the officers were ordered home in the Por@ pois. In this ship he was wrecked on a coral reef off the Australian coast, and with 94 persons spent nearly two months on a narrow sandbank only a few feet above the sea level, whilst Captain Flinders proceeded to Port Jackson for reparation.

Having fortunately escaped the fate of his chief, who on his voyage home was unjustly detained as a prisoner in Mauritius, Franklin proceeded to Canton with Captain Parkinson, who had charge of the Porpoise, and embarked on board the East Indiaman crowning the British triumph at Trafalgar, for the purpose of returning to England. This ship and other Indiamen were attacked by the French admiral, Linois, in the Straits of Malacca, but Sir Nathaniel Dance gallantly defeated his antagonist. During the engagement, Franklin acted as signal midshipman, and was of considerable service in other ways.

Shortly after his arrival in England he was appointed to the Bellona, Captain Lees, and had the charge on board the ship of the taking of the felucca of Trafalgar. It is recorded that he performed this important duty with singular coolness and intrepidity, although many of his other officers were shot around him. Indeed, out of forty commissioned men, only seven, of whom he was one, came out of the battle unscathed. He now served for two years with the Channel fleet and Rochesford squadron, and then joined the Bedford, in which ship he was present at the blockade of Flushing—off the coast of Portugal,—on the Brazil station, and on the West Indies station. In the latter, he greatly distinguished himself in a gun-boat action, in the course of which he received a slight wound. For his gallant conduct on this occasion he was promoted to the rank of lieutenant.

Having having been established, the attention of Govern@ ment was turned to Arctic discoveries, which, having been inter@ rupted during the long war; and in 1816 commenced the brilliant and remarkable series of Arctic expeditions with which Franklin's name is so honourably associated. The
but his wishes still pointed towards active employment, and consequently, when the Arctic expedition was contemplated, which he had already announced in the admiralty, he did not hesitate to command, when the Admiralty of opinion was that he was the officer best fitted to act as chief. That expedition was originated by the late Sir John Barrow, secretary to the Admiralty, who had published a plan for the discovery of the North-West Passage to India. The plan was received with favor by the council of the Royal Society, which had been referred to the council of the Royal Society was adopted.

The expedition, consisting of the Erebus and Terror, which has become the most famous of discovery in the Antarctic Seas, left England in May 1846. Unhappily its history and fate are still veiled in obscurity; this however, we know, that everything was done to render it efficient; that the officers under Sir John Franklin were men of science, and that all the information and knowledge derived from them represent their commander animated by all the ardour and spirit which characterized his early Arctic exertions.

It would have been unjust to have expected less from such a man, and as his instructions contained the usual discretion power given in these documents, there is too much reason to fear that he fell a victim to his daring attempts to achieve success. It will ever be a matter of regret, though it would have been the happier case, had the Erebus and Terror at the entrance of Wellington Channel caused the search for our countrymen to be directed principally to the north and west of Barrow's Straits; because, although the information brought home by Dr. Rae in 1854, to the effect that they had returned to the arctic seas, an immense white man in spring of 1850 on what is supposed to be Montreal Island, and, at the mouth of the Fish River, cannot be regarded as trustworthy; yet the relics of the expedition proved the correctness of their experience. The Erebus and Terror, Franklin's ships must have been yet within an area comprised within the 70th and 72nd parallels of latitude and the 97th and 100th meridians.

Another expedition, and doubtless the last, has been sent out from England in the spring of this year, under the command of a poet and diplomatist, whose progress and fate is a mystery which still shrouds the fate of the Erebus and Terror, and their crews. The expedition left Aberdeen, July 1, 1857, in the Fox, a screw yawl, under the command of the distinguished arctic explorer, Captain M'Clintock.

FRANZEN, FRANS-MICHAEL, an eminent modern Swedish poet and prosist, was born on the 9th of February, 1772, at Uleborg, in Finland, at that time a province of the Swedish crown. Finland, both before and since its combination with Sweden, though possessed of a language of its own of an entirely different character. Runeberg, at present the head of Swedish poetical literature, is a Finn, and the first effort of Franzen that attracted attention was his poetical elegy on the death of a Finn, in which the two poets were united by the symphony of a poet and a diplomatist, and passed much of his life as ambassador at Paris. The 'Atis and Camilla' of Creutz, which introduced an ease and elegance, before unknown, into Swedish poetry, and the elegy on its author by Franzen produced a commotion in the literary world of Stockholm, by the originality and vigor of its tone, which was in strong contrast to that of the school of Leopold, then dominant, who was an ingenious imitator of French models. The enigmas obtained, in spite of its originality, the great prize of the Swedish Academy. This was in 1794, at which time, and for nine years previous, Franzen had been a student at the Finnish university of Abo. In the following year he set out on a tour to Denmark, Germany, France, and England, and during which he had to witness the great fire of Copenhagen, which destroyed a third part of the city. In Paris he ventured on a piece of composition in French verse, which was printed in a French periodical, and which he reprinted thirty years afterwards in the 'Invention of his Swedish powers, founded on the tale of the revolution, 'Julie de St. Julien.' During his absence he was elected librarian to the University of Abo, and afterwards professor of literary history. After the transfer of Finland to Russia by the war of 1808, he resolved to return there, where he had been the subject of bitter satire. At first he officiated as pastor of Kuma, in the diocese of Stargraves, a parish remote from the capital, but he was afterwards minister of the church of Clara at Stockholm, where the poet Chorēs had preceded him; and in 1834 he was chosen Bishop of Hernsand. While still a resident in Finland, he had been chosen one of the eighteen of the Swedish Academy; a distinction of the same importance for a literary man in Sweden, as to be a member of the Royal Literary Academy in England. After being made a member of his society, and remained so for ten years, during which it was part of his duty to write a series of biographical notices, which were much admired for their literary merits. He appears to have resigned the secretarieship on his elevation to the bishopric of Stockholm in 1847. Leaning in his travels in Sweden gives an account of his meeting with Bishop Franzen on board of a steam-boat, when going on a visit to his northern diocese, and speaks of the general affection and veneration with which he was regarded.

Archbishop Wallin, Bishop Tegnér, and Bishop Franzen were three of the most distinguished poets of Sweden in the present century. They were all three associated in the new Swedish version of the Psalms, for which Franzen was appointed to the chair in 1814, and respecting the excellence of which there is but one voice, it being generally regarded as the best in Europe. It is singular that so little reference has been made to this fact, in the frequent discussions that have taken place on the expeditions of obtaining a new poetical version of the Psalms in English. The poetical works of Franzen were collected in five volumes, at Oebro in 1834 and subsequent years. The most successful are decly in the songs and sonnets, particularly the 'Adventures of a Christian' and 'The Northern Gallery.' His last and best work was the 'Sons of the North,' both in Sweden and Finland. Their prevailing character is sweetness. The longer narrative poems, one of which 'Sten Sture,' extends to twenty cantos and fills an octave volume, are of a somewhat dry simplicity, both of style and incident, and approach in manner to the 'Nineteenth Century.' The Franzen was regarded by Swedish writers as belonging to neither of the two rival schools of poetry in his time and country, the 'Academic' or Classical, and the 'Phosphoristic' or Natural, of which, however, the last was generally followed by the most distinguished writers. His sermons, of which four volumes were published, are unusually animated; he was also the author of some controversial writings against the doctrines of the Rationalists, called forth by the controversy respecting Strauss's 'Life of Jesus.' The chief of his two works, above mentioned, have been collected under the title of 'Minnestextknigar.' In the introductory speech before the Swedish Academy prefixed to them, the reader remarks a tone of courtly deference in speaking of Charles XII., and even of the Russian government, to avoid living under which he left Finland, the absence of which would perhaps have inspired a higher notion of the dignity of Franzen's character.

FRASERBURGH, [ABERDEENSHIRE, S. I.]

FRATRELLA, a kind of Grass belonging to the order Frangillaceae and the division Insecta. The seeds are straight, longer than deep, conic, and pointed; mandibles nearly equal, cutting edges entire, forming a straight combed surface; generally 7 to 11 lateral, 3 to 6 frontal. Wings with the first quill-feather longer than the fifth, but a little shorter than the second or third, which are equal, and the longest in the wing. Legs with the tarsi of moderate length; toes divided, and adapted for hopping and perching; claws curved and sharp.

FRANZEN, FRANS-MICHAEL, a distinguished writer of Finland, who was the author of several volumes of political and historical works, and is remembered for his portrait of Charles XII., which was engraved on a medal by C. H. H. A. Bas.

FRANKFurt, the principal town of Germany, at the mouth of the Main, and on the right bank of the Rhine, where it is joined by the Main. It is an important commercial and manufacturing center, with a population of about 600,000. The city is famous for its beer, and is also the site of the University of Frankfurt, which was established in 1379. The town is situated in the Province of Hesse, and is the capital of the Frankfurter Kreis. It is a center of trade and industry, and is also the site of the Main-Kinzig Museum and the Frankfurt School of Art. The city is also known for its Christmas market, which is one of the largest in Germany.
and also naked Seeds (Semina nudae); such as Convolvus, Opodelcas, and Loranthoeca. But there are some plants in which the germen is easily destroyed, so that the seed-bud is developed without an envelope to the seed; these, in order to distinguish them from the former, are termed Semina denudata, as Lonicera and Polygala.

Fruits may be divided, according to the analogy of the flower, into Naked and Covered (Fructus nudus et Fructus tectus), according as the germen only appears to exist, as in Lilium, or as this is surrounded by other floral parts, as in Antirrhinum. The germen itself is sometimes called a Simple Fruit (Fructus simplex), as in Nigella; when several, a compound or Multiple Fruit (Fructus multiceps), as in Rammacectus.

The parts of a Fruit are the Pericarp, the Spermatheca, the seed, and the Pulp.

The Pericarp is the transformed germen; sometimes it is united with the other persistent parts of the pistil, style, and stigma. The latter are seldom of particular importance; and all that need be said of them is that they are sometimes retained, as in Papaver, or they are more developed, as in Pulatitula. The forms of the pericarp are exceedingly diversified, but admit of no general definition: they frequently exhibit hairs, prickles, protuberances, and membranous expansions, or junctions of the ovules in their interspaces (valleculae), &c. The pericarp essentially determines the varied appearances of the fruit, by its diversity of structure. The parenchyma of the germen is developed in various ways. In the simplest cases, we find in the ovules only the embryo and its coverings, and between these a uniform layer of parenchyma, without vascular bundles, as in the lower Araceae, or traversed by a few simple bundles. In other cases only the epidermis of the outer surface is perceptible, whilst the entire parenchyma, with the epidermis of the inner surface, is succulent or fleshy, as in Atropa; or it may be, that under the epidermis of the outer surface some layers of cellular tissue are woody, whilst the underlying are fleshy; in both cases very frequently passing without determined boundary into the pulp.

In many other cases four layers are distinctly discernible, and have been named, counting from without inward, Epicarp, Mesocarp (also Sarcocarp, or Flesh, caro); and the inner under-lying portion, the Koepfera. Those varieties of structure in the fruit are most important which cause the peculiar solutions of the continuity in the fully matured condition. Hence we obtain two comprehensive classes of fruits, according as their construction causes a separation into individual parts or not. The latter may be termed the berry-like, and the former the capsular. The capsular are again divided into two groups, according as the pericarp either opens and suffers the seed to escape—Capsules; or remains closed, as enclosed or separate, or parts of the pericarp which do not again open, but firmly inclose the seed—Splitting Fruits (Sichicos), and their parts called Mericarps. The Berry-like Fruits are also subdivided in accordance with the number of the inner layers, as the more tough and solid, and the outer the more fleshy and juicy—Stone Berries (Drupes); or the reverse—True Berries (Baccas); or, lastly, all the layers appear thin and dry, or leathery (Achenia). All these forms may, with the germen from which they arise, be superior or inferior, one or many-seeded: one or many-seeded; which only require to be noticed when deviations in the structure of the germen have arisen through abortion, being otherwise self evident.

Fruits occur in the most diverse families. The mode of bursting (Dehiscentia) need not be observed. The simplest process is an apparent wholly irregular tearing open at any place, as in Nicandra: usually however the form of this dehiscence is very regular, even though it may be confined to a small part of the fruit, as in Popaver, Antirrhinum, &c.

The solution of continuity is either vertical or horizontal: in the latter case the upper part forms a kind of cover upon the seed; the capsule is termed circumscissile. In the first case, the valves separate, as in Coccus, and Pilocarcis; or separate pieces, which are termed valves. In many-coloured fruits the valves may separate entirely from the persistent sepal, as in Coccus accicosus (dehiscentia sepaliformis); or the sepal may be much smaller, as in Capsa, or divided into several parts, as in Solanum. The pericarp may be one of these lamellae on each of its margins (dehiscentia sepalica, valvulina marginis sepalor). or the sepal may remain united, adherent to the middle of the valves (dehiscentia loculisida, valvulina medio septifera). If in any of these kinds of dehiscentia a stalk-like mass of cellular tissue remains standing in the axis of the fruit, it is called the Columnella.

From what has been said, it is sufficiently evident that those solutions in the continuity are not at all dependent upon the original composition. Such a relation has been assumed; and to the line in the external circumference of the pericarp, where the edges of real or pretended carpal veins have become blended, the term (dorsal suture, has been applied. But this line is never seen on the line where the margins of one and the same carpel or similar part have become blended.

In the generality of capsular fruits, the above-mentioned fissions in the pericarp may be distinguished from one another; but they are usually very thin and membranous or leathery, or more rarely woody.

6. The Sichicos, or Splitting Fruits, are usually distinguished chiefly according to the direction in which the leaf is split. This is either parallel with the axis of the fruit, or perpendicular to it, that is, the solution of continuity is either vertical or transverse. In both, the separate parts are usually only one-seeded. In the first case the separate parts are sometimes termed Coccis or Mericarps, in the last case more commonly as Carps. This distinction, according to the texture of their layers, as dry, coriaceous, and succulent. The first (the mericarps) are proper to the families Rubiaceae, Ephorbiaceae, Labiata, Boraginaceae, Gt~...
The dilated disc, whilst in the Strawberry (Fragaria) the sweet juicy part is the receptacle.

The terms applied to the fruits of plants by botanists are very numerous. The various kinds of fruit have several names, whilst the same name has been applied to several different kinds of fruits. The following enumeration of some of these terms is given by Schleiden in his "Principles of Science," who remarks on this subject with care attention from those interested in the further development of this subject.

 Enumeration of the Various Forms of Fruit.

I. Seed naked (Senex nudum).
   A. Seed solitary.
   B. Fructifications.
   II. Simple Fruits (Fructus simplex).
      A. Capsule (Capulis).
         + Superior.
      B. Ovulaceous (Ovulae).
      C. Carpelaceous (Carpoles).
      D. Bilocular (Biloculi).
      E. Trilocular (Triloculi).
      F. Polysperma (Spermata).
      G. Exocarpium.
      H. Endocarpium.
      I. Exocarp and endocarp.
      J. Mesocarpium.
      K. Spermatophora.
      L. Fructus.
      M. Fructifera.
      N. Fructiferous plant.
      O. Fructiferous tree.
      P. Fructiferous shrub.
      Q. Fructiferous herb.
      R. Fructiferous root.
      S. Fructiferous stem.
      T. Fructiferous flower.
      U. Fructiferous fruit.
      V. Fructiferous plant.
      W. Fructiferous seed.
      X. Fructiferous pollen.
      Y. Fructiferous spore.
      Z. Fructiferous sporangium.

III. Multiple Fruits (Fructus multiples).
   A. Several Achasina.
   B. Several Baronia.
   C. Several Berloja.
   D. Several Fructifications (Fructus compartus).
      A. Capsula with a flat or cup-shaped fleshy peduncle.
      B. Spike with fleshy bracts and perianth.
   E. Several Baronia.
   F. Several Berloja.
   G. Several Fructifications (Fructus compartus).
      A. Capsula with a flat or cup-shaped fleshy peduncle.
      B. Spike with fleshy bracts and perianth.
   E. Several Baronia.
   F. Several Berloja.
   G. Several Fructifications (Fructus compartus).
      A. Capsula with a flat or cup-shaped fleshy peduncle.
      B. Spike with fleshy bracts and perianth.
   E. Several Baronia.
   F. Several Berloja.
   G. Several Fructifications (Fructus compartus).
      A. Capsula with a flat or cup-shaped fleshy peduncle.
      B. Spike with fleshy bracts and perianth.
   E. Several Baronia.
   F. Several Berloja.
   G. Several Fructifications (Fructus compartus).
      A. Capsula with a flat or cup-shaped fleshy peduncle.
      B. Spike with fleshy bracts and perianth.
   E. Several Baronia.
   F. Several Berloja.
   G. Several Fructifications (Fructus compartus).
      A. Capsula with a flat or cup-shaped fleshy peduncle.
      B. Spike with fleshy bracts and perianth.
   E. Several Baronia.
   F. Several Berloja.
   G. Several Fructifications (Fructus compartus).
      A. Capsula with a flat or cup-shaped fleshy peduncle.
      B. Spike with fleshy bracts and perianth.
   E. Several Baronia.
   F. Several Berloja.
   G. Several Fructifications (Fructus compartus).
      A. Capsula with a flat or cup-shaped fleshy peduncle.
      B. Spike with fleshy bracts and perianth.
   E. Several Baronia.
   F. Several Berloja.
   G. Several Fructifications (Fructus compartus).
      A. Capsula with a flat or cup-shaped fleshy peduncle.
      B. Spike with fleshy bracts and perianth.
   E. Several Baronia.
   F. Several Berloja.
   G. Several Fructifications (Fructus compartus).
      A. Capsula with a flat or cup-shaped fleshy peduncle.
      B. Spike with fleshy bracts and perianth.
   E. Several Baronia.
   F. Several Berloja.
   G. Several Fructifications (Fructus compartus).
      A. Capsula with a flat or cup-shaped fleshy peduncle.
      B. Spike with fleshy bracts and perianth.
   E. Several Baronia.
   F. Several Berloja.
   G. Several Fructifications (Fructus compartus).
      A. Capsula with a flat or cup-shaped fleshy peduncle.
      B. Spike with fleshy bracts and perianth.
   E. Several Baronia.
   F. Several Berloja.
   G. Several Fructifications (Fructus compartus).
      A. Capsula with a flat or cup-shaped fleshy peduncle.
      B. Spike with fleshy bracts and perianth.
   E. Several Baronia.
   F. Several Berloja.
   G. Several Fructifications (Fructus compartus).
      A. Capsula with a flat or cup-shaped fleshy peduncle.
      B. Spike with fleshy bracts and perianth.
   E. Several Baronia.
   F. Several Berloja.
   G. Several Fructifications (Fructus compartus).
      A. Capsula with a flat or cup-shaped fleshy peduncle.
      B. Spike with fleshy bracts and perianth.
   E. Several Baronia.
The antheridia are borne on branching jointed threads, called Paramenata, which rise, like the spores, from the walls of the conceptacle, and commonly fill the greater part of its cavity. Each antheridium is an elongated cell forming the terminal articulation of the branches of the paramenata, and is filled with minute orange-coloured bodies called Sporidia (by J. Agardh), closely resembling the zoospores of the lower Algæ, and like the latter endowed with spontaneous movements. Each antheridium becomes a mature, and at length are consolidated into a single spore, as in Fucus, Himanthalia, &c.

FUCACEÆ, a natural order of Algæ, or olive-coloured inarticulate Sea-Weeds, whose spores are contained in spherical centres, immersed in the substance of the frond. The root has almost always a conical disc, rarely branching or creeping. The fronds are of an olive-brown or olive-green colour, becoming darker in drying; of a tough leathery substance, and fibrous texture, tearing lengthwise with facility; dichotomous or pinnate; rarely irregularly branched, and very rare of the simple form; not infrequently, there is no distinction into parts (as stem, leaves, conceptacle), but the fructification is equally dispersed through all parts of the plants; in others (Durvillea Sarcorhynus) there is a stem ending in a phyll-like or leaf-like frond, from which the fructifications are scattered; in others (Himanthalia) there is a simple frond of small size, and a branching receptacle of fructification resembling a frond; in others (Fucus Cystoclonium) there is a branching or imperfectly leafy frond, some portions of which are wholly or partially hollow and contain the receptacles of fruit; and, finally, in the most perfect kinds (Sargassum Marginaria) there is a branching frond, well-formed mostly different and named leaves and receptacles, from which the last is set apart as organs of fructification (not formed by swelling of the stem, but forming either in the axis or along the edges of the leaves or branches. Air-vessels are present in almost all, either in bladdery swellings of the stem and branches, as in Fucus, or as distinct organs, as in Sargassum, stalked, and mostly springing from the same part as the fructification. Receptacles of the fruit, mostly more or less distinguishable from the barren portion of the frond, swollen, succulent, often filled with alimy mucus, either formed from the metamorphosed ends of the branches, or evolved from the axils or sides of the branches or leaves. Those receptacles are pierced by minute pores, which communicate with small spherical chambers formed by an introduction of the walls of the receptacle at the points where they perforate. The cells of the chamber, called Conceptacles by some writers, Scaphidia by others) contain sometimes spores, or reproductive bodies, analogous to the seeds of more perfect plants; sometimes antheridia, supposed to be the remains of the stamens; sometimes both organs in the same chamber. These chambers are formed in a single chamber. One of the surface-cells being fertilised, gradually enlarges, projects from the wall of the chamber, becomes more or less oblong, and finally is converted into a peristome, or mouth, and in some cases, the peristome is contained within the enlarged cell. At first the contents are nearly fluid, of a pale olive colour; gradually they acquire density and become more or less opaque, and at length are consolidated into a single spore, as in Fucus, Himanthalia, &c.

The frustules are easily known from all other Ollivaceous Sea-Weeds, by a character at once natural and easily ascertained, the fructification of this group, within little hollows sunk in the substance of the plant, and communicating with the surface by a pore. The order is represented in most climates, from high northern and southern latitudes to the equator. Very few species vegetate in the polar regions of the earth, none the species of Fucus and Himanthalia alone reach to the icy sea; and in the Antarctic Ocean the order is limited to Durvillea and to Sargassum. Scaphidia, a fine Algæ allied to sub-tropical forms. The British species, excluding three doubtful natives, are but fourteen; yet from the strictly social habits of several of them, they cover more surface of tidal rocks than all the other Algæ put together. It is these plants which impart the deep brown colour to the belts of rocks exposed on the rock face.

The following is a synopsis of the British genera of these plants:—

2. Halidrya.—Frond linear, pinnate, leafless. Air-vessels divided into several cells by transverse partitions.

I. SARCOSEM,—Frond furnished with distinct, stalked, serrated leaves, and simple axillary stalked air-vessels. Receptacles small, linear, tuberculated, mostly in axillary clusters or rosettes. Seeds in distinct cells. The generic name is from Sargasso, the Spanish term for masses of weed floating in the ocean in some latitudes.

1. S. vulgaris; and...

2. S. bacciferum, though both of them have been found cast on our shores, have no just claim to a place in our flora, being natives of the tropics, occasionally driven, with other tropical productions, by the currents of the Atlantic Ocean. The species of this genus are found over a wide extent of ocean, and have been generally called Gulf-Weed. They appear like floating meadows in the midst of the ocean, the name the species of Fucus, being probably support a larger number of living creatures than the most productive pasture in Great Britain. Myriads of Mollians, Radiata, Fishes, and Crustacea may be seen playing about in these masses; and the abundance of Zoophytes which find shelter in such situations can hardly be estimated. The weed is eaten in China. In the East it is used as salads, and forms a pickle.

II. HALIARUS has compressed linear fronds, pinnated with distichous branches. The air-vessels are lanceolate, stalked, divided into several cells by transverse partitions. The receptacles are terminal, stalked, cellular, pierced by numerous pores, which communicate with immersed spherical conceptacles.

III. CROTONARE has frond furnished with branch-like leaves, becoming more filiform upwards. The air-vessels are simple, arranged within the substance of the branch-like leaves consecutively. The receptacles are cylindrical, more or less lanceolate, tuberculated, and terminal. The seeds in distinct cells. The name is derived from two Greek words, signifying a little sea, and a chain.
C. articulata has a thick woody short stem, cylindrical, and is covered with numerous slender filiform branches, variously divided, and densely clothed with small spino-like awl-shaped rami (or leaves). It is found on rocks in the sea, and has the property of being indigestible when under water in a growing state. In drying it becomes nearly black, and does not adhere to paper.

The other British species of the genus are—C. granulata, C. Verticillata, and C. filiformis. The former is more a rock than a seaweed. In some cases it seems difficult to determine as to the duration of this plant. Sometimes it is annual, as the thongs are produced every year; but others say the long thongs are only receptacles, that the cup-shaped disc is perennial, and that this part is truly the plant. The cup-shaped disc or receptacle, which sends out the plant discs, is more than an inch in diameter. The branches or receptacles are in Scotland about six feet long. In Cornwall they are sometimes twenty feet long. The name in English signifies Sea-Thongs. The fruit consists of taberces immersed in the fronds, and these taberces discharge their seeds by pores, which give the thongs a spotted appearance. This is remarkably the case when, after lying on the shore for some time, every pore is covered with a yellow dot, which is the result of the plant disc which goes on, when, torn from the rock and tossed about by the waves, it lies withering in the open air.

Dr. Neil mentions that in the north of Scotland a kind of sause for fish or fowl, resembling ketchup, is made from the cup-like or fungus-like fronds of this plant and named "Sea-Thongs." (Harvey, British Marine Algae; Landsborough, British Sea-Weeds.)

FUCHSITE, a Green Mica from the Zillerthal, containing 4 per cent. of oxide of chromium. From the crystallisation of mica from salt water has been named the old species so called. The common mica has an oblique prism for its primary. Many micas when in perfect crystals have the form of a hexagonal prism, and but one axis of primary crystallisation; this last fact is the primary to be a regular hexagonal prism. This species is properly distinguished, and has been called Hexagonal Mica.

FULLER, S. MARGARET, MARCHIONESS OSSOLI, was born at Cambridge-Port, Massachusetts, United States of North America, May 23, 1810. Her father, a solicitor and a member of the Congress, perceiving her early aptitude, had her so highly educated that she was accustomed to speak of her while quite a child as "knowing more Greek and Latin than half the professors," while she herself says that she had nearly forgotten her native tongue from constantly reading other languages. The consequence was, that when she grew to womanhood she had an overpowered nervous system, was a somnambulist, very near-sighted, and in general strongly emaciated, but perfectly dogmatic, and unconquerably clever, as well as cultivated person. The sudden death of her father in September 1839, threw upon her domestic duties and obligations to which she resolutely and without affection addressed herself. She was at the age of 12, and was called the Horner Fullers. It resembles the preceding species, but is much thinner and more transparent, the midrib is more distinct, and the leafy part is narrower, although it is a more graceful plant than F. articulata.

F. articulata, Serrated Sea-Weed, is very common on all our sea-shores. It is the Sea-Weave, Bladder-Fucus, Kelph-Weave, Black-Tang of Scotland, and sometimes Lady-Wrack. In Gotland, according to Linnaeus, it is the plant of the Midsummer Night and is esteemed with a little coarse flour they give it to their hogs. In the Hebrides, chilies are dried without salt, being covered with the ashes of this plant, which abounds with salt. In Scania it is the salt that is drawn and which a root is a hard flat disc. The fronds are from 2 to 3 feet in length. The air-vessels, as large as units, are in pairs; the receptacles, in pairs, and often forked, terminate in branches. There is a variety of this which is often called Fucus Balticus. It is found among stones and moss in many ground long and loosely overflown by the tide. Lightfoot mentions that during the snow-storms in the Highlands, the red deer descend from the wild mountains to feed on this sea-weed. He mentions also that the saponaceous mucus of the vessel has been recommended to remove glandular swellings, and the calcined powder of the plant is said to be valuable as a dentifrice. The great use now made of this weed, as well as of others, is in the manufacture of kelp and iodine.

F. knobbed, known as the Horned Fucus. It is found with it in England, and is called the Horned Fucus. It resembles the preceding species, but is much thinner and more transparent, the midrib is more distinct, and the leafy part is narrower, although it is a more graceful plant than F. articulata.

F. nobilis, Knobbed-Wrack. The root is a large hard conical mass, from which spring several branches, from 2 to 4 or 6 feet in length. It is called in some places Yellow Wrack. In England it is often called Sea-Whistle, in consequence of the custom among children of converting the vessels into whistles. The air-vessels are called crackers; for which reason it is sometimes called the "Cracker" Fucus. F. Mackie is found on muddy sea-shores, usually in land-locked bays and among boulders. The frond is from 6 to 10 inches long, densely tufted; branches crowded, spreading, compressed at the base, cylindrical upwards. The venation is rather obscure, and simple, the frond in substance leathery; when dry somewhat horny.

F. canalicularus, Channeled Fucus. This is abundant on rocks on the sea-shore near high-water mark. It is perennial. Cattle are exceedingly fond of it, and never fail to browse on it in winter as soon as the tide leaves it within their reach.

VI. H. L. T. has coralline orbicular top-shaped fronds. Very long strap-shaped receptacles, repeatedly forked, spring from the centre of the frond, filled with mucus, traversed by jointed fibres, and pierced by numerous pores, which communicate with immersed spherical conceptacles, containing either parietal spores or antheridia. H. L. T., or Asian, is a rock scourer of some kind. It seems difficult to determine as to the duration of this plant. Some consider it as annual, as the thongs are produced every year; but others say the thongs are only receptacles, that the cup-shaped disc is perennial, and that this part is truly the plant. The cup-shaped disc, which sends out the plant disc, is more than an inch in diameter. The branches or receptacles are in Scotland about six feet long. In Cornwall they are sometimes twenty feet long. The name in English signifies Sea-Thongs. The fruit consists of taberces immersed in the fronds, and these taberces discharge their seeds by pores, which give the thongs a spotted appearance. This is remarkably the case when, after lying on the shore for some time, every pore is covered with a yellow dot, which is the result of the plant disc which goes on, when, torn from the rock and tossed about by the waves, it lies withering in the open air. Dr. Neil mentions that in the north of Scotland a kind of sause for fish or fowl, resembling ketchup, is made from the cup-like or fungus-like fronds of this plant and named "Sea-Thongs." (Harvey, British Marine Algae; Landsborough, British Sea-Weeds.)
The writings of Margaret Fuller will have no permanent value in themselves, either for their literary merits, their social opinions, or their estimates of character, of art, or of literature. But they will retain a certain value, in connection with the history of their author, as illustrative of a peculiar phase of society in America during the second quarter of the 19th century. Margaret Fuller herself was undoubtedly a woman of great ability as well as of considerable attainments, but she had thoroughly studied a single subject, and her writings are all disfigured by dogmatism, assumption, and self-reference. In them you often come upon a striking and apparently original thought; but if the thought was not put on for a moment, it appeared to show its uncommonness mainly to peculiarity of expression; and sometimes these peculiarities degenerate into grotesqueness. Had her life been spared however there can be little doubt that what was strange, and almost repulsive in her first volumes, and in her later and more refined works, both of these works we believe, were reprinted in London.

In the spring of 1846 she put in execution a cherished scheme of a prolonged European tour. She first visited England, where she stayed some time, and obtained introductions to many of the literary notabilities, whom she describes and criticises in her letters with a most amusing air of superiority. In Paris she also remained for some time, and formed the acquaintance of Madame Dudevant, &c. But Italy was the country she most desired to visit, and thither she next proceeded—little dreaming to what a strange conjunction all her theories of woman's rights and slams and missions there would be brought. For a brief space she revelled in the enjoyment of the scenery, the climate, and the boundless topography of Italy. But it must be confessed that a portion of her time was occupied in rendering herself conspicuous by her open and resolute, though somewhat imprudent avowal of extreme democratic opinions, and intercourse with persons obnoxious to the authorities on account of their political sentiments. She had been involved in an affair of a very different sort than not less exciting nature. She met by accident at Genoa, in St. Peter's, Rome, while separated from her friends by the crowd, a young Italian gentleman; he behaved with a courtesy that charmed her, his intimacy was easy, and though he was many years her junior, so utterly uneducated that he had scarcely ever looked into a book, and without any kind of intellectual pretensions, the strong-minded worshipper of intellect with a very fair fortune and a handsome figure, the Marquis Ossoli, though of a noble family, had a very small patrimony, and that was in the hands of trustees. Moreover his family were devoted Roman Catholics, and his elder brothers held high appointments under the papal government; they would of course be bitterly incensed at his marrying a lady not of that faith, and especially one who was an avowed liberal. He therefore urged that the marriage should be strictly concealed; and to this she submitted. They were married in December 1847, and Madame Ossoli remained in Rome, occupied with her munificent plan for a girls' school; indeed she was not till more than a year after the birth of a son that even her own mother was informed of the marriage. The sudden ascendency of liberalism in Rome however altered matters; the Marquis left, and on his return to Madrid, took, as it would seem, to bear evidence of it. She had to come from him to various Italian liberals; and she had converted her husband to her own political creed. When the revolution broke out her husband threw himself heartily into the movement; and she shrunk from none of the duties which her position and her opinions seemed to have devolved upon her. During the siege of Rome she was occupied as nurse, having charge of one of the hospitals opened by the Roman Commission for the succour of the wounded, and acted with a noble disregard of toil and danger. Thus she much added to her greatest kindness in her self-imposed task. The fall of the republic compelled her to leave Rome; and with her husband and her child, she, after staying the winter at Florence, embarked at Leghorn in May 1850, on board the Elisabeth, for America. From the first the voyage was uncomfortable to the captain died soon after the ship sailed; the weather was throughout stormy; and though the vessel reached the American coast, it was only to be wrecked there, having stranded on Cape Hatteras. Long Island. A few of the passengers and crew were saved, but Margaret Fuller, her husband, and child were among the drowned. The body of her child came ashore, but her own tomb was the ocean.

from the parent oell, as, for instance, In Peniciltium
In others the thread-like cells form a spherical
swelling at the extremity, from which project a number of
such prolongations, each of which contains a spore, while
the whole forms a divided sporangium, as, for instance, in
Mucor and PenicUlhm.
"In others (Gasteromycetcs, the ventricular Fungi) the
thread-like cells combine
into pointed, or non-pointed,
variously shaped sporocarps ; in or upon which are spores,
of the development of which we know nothing.
After the
scattering of the spores, the thread-like cells often remain as
tender wool, as in the Trichiacece, or as a delicate network
(eapilliiinm), as, for instance, in Stemoniti* cribraria ; and
the external capsule (uterus peridium) generally composed
of fine filamentous cells, is then dissolved, or bursts in different regular ways, as in Arcyria and Geattrum.
"In the most highly developed Fungi {Hymenomycetes,
membraneous Fungi), elongated pouch-like cells (probably
only the ends of the interwoven filiform fungus-cells, developed into the sporocarps, or cells formed at the ends of these
cells) combine oy arrangement side by side so closely as to
form a membrane (hymenium).
Some of the cells of this
membrane enlarge considerably (sporangia), and send out
from one to six points at their free extremity, in each of
which a spore is developed.
The filiform cells of the fungus
then either form round masses^ closed in all round (sporocarps), with cavities in their interior, the walls of which
are clothed by the hymenium, or they form definitely
arranged columns in Merxsma, tubes in Polypcrus, or lamellae
in DtedaUa and Agarieut, which are clothed by the hymenium, as in the Hymenomycetes.
Of the latter we only know,
with any amount of accuracy, the law of development relating
to the Toadstools, and more especially that of the Agaricinea.
arising

in the air.

and Botryiia.

plants.

In these latter there are formed, at definite parts of the floecnlent mycelium, small hollow heads (volvas), at the bottom

the cavity of which there grows a corpuscle, shortly
pedunculated below, and enlarged into a spherical form at
the top.
In the lower part of this protuberance a horizontal
circular cavity is formed, to the upper surface of which are
attached the tubes, lamellae, &c, which bear the hymenium.
The bottom of the cavity is only formed by a membrane
(indnsiuro), which is either separated from the pedicel on its
farther development, or, loosening itself from it and the
upper part at the same time, remains as a membranous ring
(aonulus) upon the stalk.
The upper part, which supports
the hymenium on its lower surface, dilates subsequently,
and appears as an umbrella-like expansion, called the cap
(pileus).
The whole then breaks through the volva, which
of

very soon dissolved."
During their growth the same Fungi assume very different forms and appearances.
It thus happens that the same
species has not only been described under different specific
names, but even referred to different genera. Fries states
that he has traced no less than eight genera of different
authors to mere degenerations or imperfect states of Thekphora tulphurea. Nees von Esenbeck also states that the
is

same fungoid matter which produces Sclerotium mycetospora
in the winter, developes Agaricus volvaceus in the summer.
Professor Henslow has also shown that some of the supposed
species of Urcdo are forms of Puccinia, Aregma, &c.
Kiitang, in an essay on the ' Transformations of Plants,' carries
his views on this subject very far, and maintains that according to different circumstances the same species will produce
Algce, Fungi, Lichens, or Mosses.
In the article Entofhyta, S. 2, will be found an account
of the plants growing on man and living animals.
Many of
these are Fungi.
Professor Balfour, in his ' Class-Book of
Botany,' gives the following account of diseases in plants
produced by Fungi:
* The attacks of Parasitic Fungi cause extensive injury
and disease in plants.
Some think that the spores of Fungi
coming into contact with the plant act both as the predisposing and exciting cause of disease j others, perhaps more
correctly, think that some change is first produced in the
cells of the plant, which enables the spores to find a nidus,
and then the disease goes on rapidly, assuming a peculiar
type on account of the presence of the fungus in the same
way as vegetable organisms found in diseases of the skin are
not to be looked upon as the origin of the disease, but as
being developed in textures previously morbid, and as giving
often a peculiar character to the disease. Many of the
diseases of cultivated crops are attributed to Fungi.
The
•pores of Fungi are very minute, and are constantly floating

the same fungus assumes seem to vary sometimes according
to the plant on which it grows.
The disease called Bunt,
Smut-Balls, or Pepper-Brand, is occasioned bv the plant called
Uredo caries by De Candolle, and Uredo faetida by Bauer.
It attacks the grains of wheat, and may be detected in them
in their earliest state.
It consists of extremely minute
globules of a dark colour, at first attached to a thread-like
matter or mycelium. Bauer estimates the diameter of each
of the globules at l-1600th of an inch, and consequently a
grain of wheat (reckoned at less than 1-1 000th of a cubic
inch) would contain four millions such spores. The spores,
or powdery matter, have a disgusting odour ; hence the specific
name given to it. The disease is propagated by contact.
Steeping the grain is recommended by some as a means of
prevention, and alkaline solutions have been suggested as a
remedy.
Uredo linearis, which is met with also in this
disease, is considered as being a young state of the Mildewplant.
Another disease called Smut, or Dust-Brand, is
caused by a fungus called Uredo segetum. It resembles the
Bunt fungus in colour and shape, but its spores are not half
so large, and it does not possess a fetid odour.
This fungus
destroys the ear of corn by first causing the innermost parts
of the flower to become abortive, while the pedicels on which
these are seated swell and become very fleshy.
The fungus
then consumes the whole of this fleshy mass, and at length
appears between the chaff-scales in the form of a black sootlike powder.
It is said also to attack the stem and leaves.
When ripe the spores burst through the epidermis, and are
dispersed in the form of a black powder like charcoal. The
spore is 1 -2800th of an inch in diameter. Smut is rare in
wheat ; it is common in barley, and more so in oats. It is
also seen in many grasses, such as A rrhenatherum avenaceum.
The disease denominated Rust, Red Rag, Red Robin, and
Red Gum, is caused by a fungus called Uredo rubigo. It
forms yellow and brown oval spots and blotches upon the
stem, leaves, and chaff. The spores burst through the epidermis and are dispersed as very minute grains. The disease
is common in corn and in grasses.
Mildew is a disease
caused by a fungus denominated Puccinia graminis. The
ripe spore-cases of this plant are small dark-brown clubshaped bodies, their thicker end being divided into two
chambers, each filled with minute spores, and their lower
end tapering into a fine stalk. The sori, or clusters of sporecases, burst through the epidermis sometimes in vast numbers.
The minute spores seem to enter the plant by the
stomata. Some think that they, as well as other minute
spores, are absorbed by the roots.
The disease attacks
wheat. Spring wheat is less liable to this disease than
winter wheat, and heavy soils are less subject to it than
light ones.
Many have supposed that the Barberry is in
some way connected with the production of Mildew. This
idea has been proved to be erroneous by the experiments of
Standinger, near Hamburg, and of Hornemann at Copenhagen.
Unger entertains the idea that blight, mildew, and smut are
to be considered as exanthematous diseases of plants caused
by the spores of Fungi entering the stomata.
" Henslow has shown by experiment that, if the diseased
seeds of wheat be steeped in a solution of sulphate of copper,
they will not produce diseased grain, and that the sulphate
of copper does no injury to their germination.
The solution
used is one ounce of sulphate of copper to a gallon of water
for every bushel of wheat.
Grain also steeped in hot water
does not reproduce these fungoid diseases. In East Lothian,
with the view of preventing smut, seed-wheat is often
steeped in stale urine, and afterwards some newly slaked
lime is sifted on it. Sometimes a solution of salt is used as
a pickle. FoUrcroy and Vauquelin ascertained by analyses
that blighted wheat contained an acrid oil, putrid gluten,
charcoal, phosphoric acid, phosphate of ammonia and magnesia, phosphate of lime, and no traces of starch.
As
regards Bunt or Pepper-Brand, Henslow remarks, that upon
simply immersing the grain in water the infected seeds float,
and on the water being poured out, nothing but the sound
ones remain in the vessel. This simple process of separation
is not however perfectly effective, because in thrashing the

wheat many of the infected grains are crushed, and the spores are dispersed in the form of fine powder which adheres obstinately to the sound grain, by means of an oily or glutinous layer in which it is enveloped in the grain. In order to reach them thoroughly, it has been considered useful to add some alkaline key to the water in which they are washed. The alkali unites with the oil and forms a soapy matter. Lime has been used for this purpose, saponified potash, substances capable of saponification, and even lime-water have been employed; other matters, as sulphate of copper, act by destroying the vegetating power of the Fungi.

Mr. Ellis, of Barning, Kent, says that the irreversible process by which the wheat is attacked and whitened is accelerated by the addition of a very small quantity of alkali immersed in boiling water, and afterwards drying it with lime. The wheat placed in a colander or in a basket is immersed in boiling water for a few seconds, just long enough to wet it completely, it is then immediately dipped in cold water, afterwards dried with line, mixed with other wheat, and sown. By this means the wheat was always found to be cured of smut, while the vegetating principle was uninjured, great care being taken that the water was boiling, and that the wheat taken out of the water as soon as completely wetted. Mr. Ellis tried an experiment on a bushel of blackest wheat he could procure, which he divided into sixteen equal parts, sowing them all the same day, but with different treatment. The result at harvest was that the wheat not treated in this linear proportion produced not 100, while that dipped in boiling water and lined had not a black ear in several thousands which were examined. Many other species of Uredo as well as Ustilago give rise to diseases. They receive their names from the plant that is affected, the parts of the plant, and the colour of the disease, as is shown by the fact that the same species presents various forms according to the situation in which it grows. *Ustilago Maydis*, a maize smut, is a fungus which gives rise to prothecomes on different parts of the maize. The stem, upper leaves, and especially the bracts become immeasurably swollen when attacked by this disease, and the ovaries, anthers, and male blossoms are not exempt. The parts affected are at first white tinged with red, smooth and juicy. The cellular tissue increases in size, and is nourished by raising the mycelium and spores. The spores are twice as large in linear measure as those of the oat smut. At first the small balls contain a dark strong-smelling fluid, but ultimately the masses become dry, and present a quantity of dark dust mixed with irregular threads. *Ustilago vittata* causes disease in grasses in India. The spores of *Ustilago hypolytes* also cause disease in grasses. The spores are black and round, and the disease they occasion is denominated Oidium. There is no well-defined line of separation between the classes of Oidiums and the Fungi. A species of *Depeza* or *Septoria* sometimes produces disease in the knots of wheat. Various species of *Eurostilago*, *E. graminis*, *E. adunca*, and *E. biscria* give rise to kinds of mildew. Erysiphe is often met with in common pea crops. Some say that Oidiums are merely particular states of Erysiphe. The plant producing mildew in the rice is *Oidium Tuckeri* of Berkeley. Other species of Oidium probably cause mildew in the peach, rose, hop, pea, and onion. For destroying the mildew in vine sulphur is recommended to be dusted on them. Some also use a solution of hydro-sulphate of lime, made by boiling sulphur and lime in water. A fungus called *Rhizoctona Maii* is said to grow on the roots of apples, pears, and quinces, and to cause destruction to the trees. Ergot is a monstrous state of the grain, in which the enlarged and diseased ovary protrudes in a curved form resembling a cock's spur, hence the name from the French 'ergot,' meaning a spur. The ovary is black externally, spiny internally, and contains much oily matter. Some consider it as produced by the attack of a fungus, which causes the ovoid condition in the ovaries. The disease is usually met with in the grain, but the name of spurred rye is applied to it. It sometimes occurs in wheat and barley, and it has also been noticed in *Lotus perennis*, *L. arvensis*, *Poa acta praenitas*, *Phleum pratense*, *P. pratense* ssp. *hemilepidotum*, *P. pratense* ssp. *aureomarginatum*, *P. pratense* ssp. *arundinaceus*, and *Alopecurus agrestis*. Ergot consists of a very dense tissue formed by polygonal cells, united intimately with one another, and filled with an oily fluid. It is developed in the uninpregnated ovule of rye, for although extremely attacked by the entophyte and rendered difficult of recognition, the integuments of the ovule increase without completely losing the form which they would have assumed, if they had grown into a true grain, inititating in this respect the ovaries of wheat, in which *Tilletia caries* (Fries) has replaced the seed. The solid mass which has been called *Sclerotium clavus* by De Candolle, and the flamentous portion called *Sphaeria* by Leveillé and Féé, and *Eryotatia* by Queckett, are only, properly speaking, organs of vegetation. They are produced by imperfect spores, resembling an elegant Spharina, probably that called by Fries *Cordyigo purpurea*. This plant has been seen by Schumacher in diseased cereal grains, and it has been detected by Roussel in *Sclerotium piceum* and Calamagrostis, and by Durner in Ergot of Rye. Tulasne has shown that this Cordyigo is produced from the Ergot when it is allowed to vegetate. Ergot of Grasses and Ergot of *Cyperaceae*, according to Tulasne, do not belong to the same vegetable species. Rye, affected with this disease, when used as bread, is very prejudicial. The Abbé Testier showed that Ergot caused gangrene in animals that fed on it, and many instances are recorded of gangrene of the extremities occurring in persons who had lived on diseased rye. Ergot is said to prevail in rye grown on wet and stiff land.

"The disease which has recently attacked the Potato in various parts of the world is by many attributed to the attack of a fungus called *Erysiphes piceum* by Berkley, who describes the fungus as *Botrixia infestans*. The spores are supposed to enter the stomata and to cause disease in the leaves in the first instance, which afterwards extends to the tubers. The effects produced on the leaves resemble those of *Botrytis* in *Lettuce*. The fungus is a poisonous, toxic, and aciditious, such as hydrochloric, sulphuric, and nitric acids. Berkeley attributes the Potato disease entirely to *Fungi*. He states that the disease commenced in the leaves. They were attacked by the mold, which ran its course in a few hours; and from the rapidity with which it so far spread, the period for examination of the leaves had often passed over. The fungus generated does not live on decayed or decaying matter, but is one which produces decay, and renders the plants unmarketable; and it has been shown that it is the prevention of the elaboration of the sap in the leaves, obstructing the admission of air and the emission of transpirated fluids. The stem is thus overcharged with moisture, and ultimately rots, while every source of nutrition is cut off from the half-ripe tubers. The atmospheric conditions during the late disease made the fungus spread rapidly.

"While there is no doubt that the *Botrixia* is developed in the progress of the Potato disease, the question arises whether or not it is the originating force, or whether it is to be set down as the phenomena, that changes are induced in the cells of the potato by cultivation which render the leaves liable to disease. Atmospheric influences are thus enabled to act upon them, so as to cause alterations of internal function. This influences the *Botrixia*, accelerates the morbid action, and causes it to assume a peculiar form. In this way high cultivation, atmospheric influences, and *Fungi* all contribute to cause disease. In the Potato disease of 1846, Hartig says that brown granular matter was deposited in the cells, first in those near the epidermis, then the cellular walls lost their transparency, and the cells could no longer be isolated by boiling water; next the cell-wall was destroyed, and small cavities were formed in the midst of the tissues, in which were agglomerated grains of starch, and finally parasitic organisms appeared in the cavities. The vegetable parasites developed were *Polyactis alba*, *Fusisporium solani*, *F. candidissimum*, *F. candidissimus*, and *Ergotum violaceum*. When the disease had advanced insects were also present."

"Crum attributed the disease of the tubers of the Potato to rupture of the starch cells, and mixture of their contents with nitrogenous matter, thus causing fermentation, as in the apple and grape. Solly objects to the fungus theory, and says that this matter is necessary for the growth of *Fungi*. He thinks that the disease is caused by the presence of putrefying animal matter in the stem, just below the surface of the soil, that this has suffused the different conditions between vital and chemical forces, and induces decomposition by a process of fermentation. The asoiled matter, in a condition to act as ferment, is produced by the state of the season, by deficiency of light, and by other meteorological causes. Analyses show that the constituents of the diseased
potato undergo a rapid and important change. Dr. Lyon Playfair and Mr. Phillips found that the amount of albumen and gisten decreased from 8:24 in the sound potato to 92 in the diseased; and when the disease advanced they finally disappeared.

Mitscherlich says that the change which cellulose undergoes by the action of a peculiar ferment is characteristic of the same nature. The destroying agent is obtained when half putrid potatoes cut up into small pieces, are immersed in water, and fresh potatoes, cut in slices, added to it; when these are decomposed, a portion of the liquid may be treated with water, and more slices of potato added, which soon become decomposed, and in this manner increase the activity of the liquid. Hence, just as in the fermentation of an infusion of malt, the yeast, the fermentative fungus, becomes augmented, so does the ferment increase. It only acts upon the cellulose, which forms the walls of the starch-cells of the potato; first the cells separate from each other, so that ammons us with a convenient means of obtaining the cells with their contents in an isolated state, and facilitating their examination; the walls of the cells are subsequently also dissolved, and the starch-particles fall out: in this manner, in 24 hours, a solution is obtained, which can be used in the same manner as we have just described. In this case, that portion can be removed by a pair of forceps, the hard mass of the potato lying beneath the softened layer, so that this process takes place successively from the outside towards the interior, not by the whole of the potato being used, but by taking up the most external portion. Exactly the same process as that which we can produce spontaneously, he says, occurs in the Potato disease, which during late years has done so much mischief. In consequence of the death of the state, is decomposed; and the liquid, which the Author had kept for a long time in contact with one of the diseased potatoes, immediately produced the decomposition of a sound one. This decomposition is, therefore, he says, not the disease itself, but merely a consequence of the dying or the previous death of the entire plant, and just as it is well known in the case of other plants that they die when the apices of their roots are too strongly cooled, so may a sudden cold rain following a long warm winter produce a similar condition of the potato plant. It is only after decay has commenced that Fungi and insects attack the plant.

Lieber attributed the Potato disease to diminished or suppressed transpiration, depending upon the hygroscopic state of the surrounding air. This intoxicating property, he said, in regard to the Hop hight, in which the disease is traced to the want of correspondence between absorption and transpiration, and a consequent stagnation and decomposition of the juices. The same thing, he thinks, takes place in the case of the potatoes, which are loaded with moisture; and he shows that in 1845 and 1846, when the disease overran Europe, damp, cold, and rainy weather followed heat and drought just at the period of the most luxuriant growth of the potato. The vessels and cells became charged with fluids; and, owing to the depressed transpiration, there was stagnation of the sap and death.

Fungi and putrefaction are, according to him, the consequences of the death of the plant. Klotzsch proposes to check the Potato disease by planting off the extremity points of the branches and twigs to the extent of half an inch downwards when the plants have attained the height of six or nine inches above the soil, and to repeat this on every branch or twig on the tenth or the eleventh week. This check to the stem and branches, he thinks, will direct the nutrient matters in the direction of the increase and multiplication of subterrestrial as well as aerial branches. This leads to increased development of tuber, and strengthens the leaves and stalks. Tonnelle, Lomba, of Namur, says that he has noticed that the disease begins by the leaves after flowering with a very sharp sickle, and then covering the ground with earth to the depth of not less than an inch and a half. The top dressing thus applied was not disturbed till the plant had grown, in which case the leaves withered being cut. It is said that the tubers acquired a good size and were of excellent quality. If these facts are true, it would appear that, while leaves are necessary to the development of tubers, the latter on acquiring a certain size can continue their growth by their own proper and unassisted vitality. The general conclusions to be drawn from all that has been said relative to the Potato disease are, that changes are induced in the cells and vessels of the potato by certain obscure meteorological and epidemic causes; that an alteration takes place in the cellulose and in the contents of the cells, which specifically leads to decay; that parasitic Fungi find a nidus in the decaying organic matter, so as to accelerate and give a character to the disease; and that, as yet, no remedy has been devised for its suppression.

For an account of the Fungi supposed to produce Dry-Rot in timber see the article Dry-Rot.

In many parts of the world the Fungi afford a supply of food to the appetite of man. Although only a dozen species are to be found in the markets of London, and only the common Mushroom, Truffle, and Morel are eaten in Paris; in Italy and other parts of Europe, a large number of species are consumed. [Abercrombe.] Dr. Basham, in his work on the "Excellent Fungi of England," gives descriptions and drawings of the following species of British Fungi as which may be used as food:—

To great caution however cannot be employed in distinguishing the edible from the poisonous species. In the markets of Rome an Inspector of Fungi is appointed, in whose duty it is to examine the products offered for sale, and none are allowed to be sold but with his express sanction. But it would appear, from a case quoted in Lindley's 'Vegetable Kingdom,' that Fungi which are usually innocuous may, under certain circumstances, become poisonous. The instance of a fungus common in this country, which after years shone with silver was the Agaricus perenatus, a species sold in Covent Garden under the name of Bliewitt, and which all writers agree in regarding as perfectly safe from danger. The poisonous principles produced in the Fungi have sometimes been employed in medicine, one instance of which is given above in the Ergot. The action of a species of Bovista has been found similar to that of chloroform. [Bovista, S. 1.] The Amanita muscaria possesses an intoxicating property, which is employed by northern nations as an inebriant. The following is the account of Langeron, as given by Dr. Greville:—

'This variety of Amanita muscaria is used by the inhabitants of the north-eastern parts of Asia in the same manner as Morina, arachis and other plants of the same nature. Such Fungi are found most plentifully about Wischus, Kamchatka, and Willowa Dereesa, and are very abundant in some seasons and scarce in others. They are collected in the hottest months, and hung up by a string to dry in the air; some dry of themselves on the ground, and are said to be far more narcotic than those artificially preserved. Small deep-colored specimens thickly covered with warts are also said to be more powerful than those of a larger size. And a colonel, who was asked to take the fungus to roll it up like a bolus and swallow it without chewing, which the Kamchatkadales say would disorder the stomach. It is sometimes eaten fresh in soups and sauces, and then loses much of its intoxicating property. When steeped in the juice of the berries of Vaccinium uliginosum its effects are those of a strong wine. One large or small two Fungi are a common dose to produce a pleasant intoxication for a whole day, particularly if water and a little drunk and filtered. To sum up the Japanese narcotic principle. The desired effect comes on from one to two hours after taking the fungus. Giddiness and drunkenness result in the same manner as from wine or spirits: cheerful emotions of the mind are first produced, the countenance becomes flushed, and the whole body throws off at last an entire loss of consciousness. It renders some remarkably active, and proves highly stimulating to muscular exertion. By too large a dose violent spasmodic effects are produced. So very exciting to the nervous system in many individuals is this fungus that the effects are often very
ludicrous. If a person under its influence wishes to step over a straw or a small stick, he takes a stride or a jump sufficient to bring the foot of a tree cannot keep silence or secrets, and one fond of music is perpetually singing. The most singular effect of the *Amanita* is the influence it possesses over the urine. It is said that from time immemorial the inhabitants have known that the fungus imparts an intoxicating quality to that secretion, which continues for a considerable time after taking it. For instance, a man moderately intoxicated to-day will by the morning have slept himself sober, but (as is the custom) by taking a tea-cup of his urine he will be more powerfully affected. On the preceding days, therefore, it is certainly not uncommon for confirmed drunkards to preserve their urine as a precious liquor against a scarcity of the fungus. The intoxicating property of the urine is certainly not being propagated, for everyone who partakes of it, has his urine similarly affected. Thus, with a very few *Amanita* a party of drunkards may keep up their debauch for a week. Dr. Langendorf mentions that, by means of the second person taking the urine of the first, the third of the second, and so on, the intoxication may be propagated through five individuals."

*Fungi* are often phosphorescent. The light given out by species of *Rhizomorpha* in the coal-mines of Dresden is described as giving them the appearance of an enchanted castle. *Amanites* are found growing on the streets of Britania in Brazil, is highly luminous. The same phenomenon has been observed in *A. olearius* in the south of Europe, and in two species of *Fungi* at Swau River. Dr. Hooker describes lycopodium growing upon decaying wood in the forests of the Sikkim Himalayas.

It is generally stated that *Fungi* differ from the rest of the vegetable kingdom, in the absorption of oxygen and the discharge of carbonic acid gas. In experiments which have been performed, it has been found that it is well known that the tissues of *Fungi* are easily decomposable, and it is more probable that the absorption of oxygen, and the giving out of carbonic acid gas is the result of decay, rather than of the true growth of the plant. The following substances are decomposed by *Fungi* in the following order:

The natural connection of the germination of the fungus with the development of *Fungi* is the occurrence of vegetable cells, referred to this order, in liquids undergoing fermentation. During the conversion of malt into beer, plant-cells are constantly observed to be present, and these have been described as a plant, under the name of *Fusel-organism*. They are prepared by a liquid known as flax, as now carried on at Belfast, Professor Allman has observed present cells resembling those of *Saccharomyces*. Whether these are true plant-cells or not, is still a question; and it is still more a question as to whether they have anything to do with the changes going on in the solutions in which they occur. They are probably a result, and not the cause, of fermentation. These cells have not escaped the observation of Schleiden, and the following is his account of them:

"In the last place, I must mention a highly interesting analogy, which, when more accurately examined, may perhaps one day lead to the most satisfactory explanation of the process of cell-formation—I mean vinous fermentation. We have seen that the sugar which passes into dry, and a nitrogenous matter, as a cytoplasm, are present. At a certain temperature, which is perhaps necessary to the chemical activity of the nucor, there originate, without, as it appears, the influences of the living plant, a process of cell-formation (the origin of the child being procured), and it appears that it is only the vegetation of these cells which produces the peculiar changes that occur in the fluid. Whether this organism is really a fungus, is a matter of individual opinion. But, through the activity of its vital processes, determines the process of fermentation, deserves to be accurately determined."

I will here add my own observations on these fermentations, as follows: I bruised some currants with sugar, and having pressed the juice through a cloth diluted it with water and filtered through folded paper. The fluid was bright red, quite clear and transparent, and, under the microscope, shows fermentation vapours, but possesses a number of drops of a pure clear oil. At the end of twenty-four hours the whole fluid was opalescent, and presented, under the microscope, a number of granules suspended in it. On the second day these granules had greatly increased, and there appeared amongst them perfectly-formed ferment-cells. There also appeared, now and then, vesicles of carboxylic acid gas. On the fourth day fermentation was very active. At the bottom of the vessel and on the surface of the fluid, yeast had formed; but these yeasts consisted of single cells, or occasionally in short chains, so that it was not the slightest possibility that the view could be observed the way in which one cell was formed from another. The ferment-cells do not in this state permit of a distinction between the contents and the membrane of the cell. In the midst of the cell there is a transparent spot, but whether hollow, or a solid nucleus, I could not decide.

The remaining parts appeared entirely homogenous, yellowish like a nitrogenous substance, sometimes mixed with small solitary granules. In a similar way, a solution of sugar with water was examined, and similar results. Other results were obtained in the following way:—Pare white protein (albumen) from the white of an egg, was dried, and rubbed down with sugar, and left to ferment: the fluid at first was perfectly clear. On the third day, the small portions of albumen, and the sugar, were heated together, in a vessel of glass, to a sharply angular aspect, assumed partly a granular aspect, and some a more or less rounded form. These globules showed an active molecular motion, and some appeared strangely together. On the fourth day they had taken the shape of spheroidal cells, which were either solitary, or arranged together in a line with a tendency to the formation of branched fibres. These cells were not more than one-third of the diameter of ordinary ferment-cells. An active fermentation was exhibited. The globules were given out from the protein-granules and the linear cells. Proper ferment-cells did not make their appearance. Fluid albumen, mixed with sugar, and filtered, became thickened on the second day, and contained little granules of albumen, as well as sugar, and these globules resembled that exhibited by the preceding, except that there were developed a few true ferment-cells. Protein moistened with water displayed the same appearances as when mixed with sugar and water; ultimately putrefaction came on, and the development of *Infusoria*, and the vestiges of the vegetable, was given out a large round flat body (a cytoplast)!

The following arrangement of the *Fungi* is given in Lindley's 'Vegetable Kingdom':—

GADELENTZ. [Elzach.]

GADBURY, [Duckw.]

GARTNER, or GÄRTNER, FRIEDRICH VON, architect, was born at Cobleslow in 1799, and was the son of Johann Andreas Gartner. Brought to Munich at an early age, he received his general scientific education, and in 1809 entered the Academy of Arts in order to devote himself specially to architecture. After three years he went to Paris to enter the Academy there; and here he enlarged his knowledge under the guidance of Perder. France had been during many years regarded as the school of Germany in art; for German art was then only about to reassert independent character, such as under Gärtnor and other artists it soon acquired. In 1814 Gärtnor went to Italy, where he remained four years. He visited Rome, Naples, and other places of general interest, but would appear to have devoted himself to the antique monuments as much as to later works, although it is the character of the Byzantine and early Italian styles to which the designs in his own buildings are most closely allied. He specially studied the ruins in Sicily, including those at Garegnos, Segesta, and Taormina, which he drew and published in lithography, in 1819, in a work entitled "Views of the best-preserved Greek Monuments of Sicily, with Explanatory Text." In 1819 also he came to England, and was engaged in connexion with the restoration here; but in 1812, when seeing the restoration of the Munich Academy, he was from that time engaged in Bavaria. Well qualified by his studies and taste to co-operate in the great revival fostered by the Crown Prince (afterwards Louis of Bavaria), Gärtnor became connected with several important branches of manufacture. The superiority in form and character attained in the works of the porcelain factory, of which he became director in 1822, was due to him, as also in great part was the revival of glass-painting. In 1820 the elevation of his character was at its height; and in the same year he was appointed to the post of architect at Regensburg. In 1825 he commenced the Blinden-Institut. Amongst his other buildings at the same time, or subsequently, were the University, the Erziehungshaus, the Domstift, the Priester-Seminar, the Salzamt, the Ludwiger-thor, and the Feldmarener-Bezirke, all in Munich; the church of St. Michael, in Wittenbach, the pump-room at Kissingen, and the Befreiungsstalle at Kelheim—a great monument in the form of a ruin, designed to commemorate the liberation of Germany. In 1836 Gärtnor accompanied the king to Athens to study its monuments and there remained three years. He was appointed the first Resident, or palace, for King Otho. At Athens he re-opened the quarries of Pentelic marble, said to have been forgotten since the time of Hadrian. On his return he was appointed oberbaeherr, or architect to the court, and received the order of Civil Merit of the Crown of Bavaria; and on the departure of Cornelius for Berlin in 1841, he was made Director of the Academy of Arts. In addition to the works there mentioned, Gärtnor was architect of the Pompejan Hause at Aschaffenburg—one of those efforts to collect a series of examples of style, through which, in consequence of that aim, the value of King Louis's still great services to art was rediscovered. Gärtnor also restored the luthor, and portions of the cathedrals at Regensburg and Bamberg. He died on 21st of April, 1847, aged fifty-five years.

Gärtnor's style, as described by Raccnynk ("Histoire de l'Art Moderne eu Allemagne"), is one which "recalls the idea of the Byzantine; which, as a general statement, is correct. The University and the Bibliothek have here a curve order of design, and there is an intercolumniation in the arch-headed window, divided into two lights by a column, and avoids the characteristics of the late Italian styles,—while ornament of original character is freely introduced, and there is a tendency to think of Munich for interior design in buildings, and the influence of which has spread even to this country, is due to Gärtnor. A publication of his designs was commenced about 1844 or 1845.
to impart the method to any one person intending to become a

Thus baffled, Gallaudet was compelled to try Paris. Here he met from the Abbé Sicard a warm welcome. Everything was ready for the opening of his school, and every means that could be devised was used to accelerate his acquisition of the desired knowledge. He was able to return to America before the close of 1816, and the Abbé Sicard cheerfully consented to let him have the notes which had been left behind of the pupils, and was then one of the most valued teachers of the institution (he had indeed already been designated its "glory and support"), accompanying him to America. During his absence in Europe, the society had been incorporated; Mr. Gallaudet was appointed the first president, and Le Clerc being his head assistant, on the 16th of April, 1817, "The American Asylum for the Deaf and Dumb," at Hartford, Connecticut, was formally opened.

Mr. Gallaudet took the life of the asylum up to 1830, when he resigned from failing health. His devotion to his duties had been most exemplary, and his success as a teacher, we are told, was "uniform and pre-eminent." The system which he in conjunction with M. le Clerc ultimately established, and which has been adopted in the other asylums (of which there are now fourteen) in the United States, was founded on that of the Abbé Sicard, but with very considerable modifications. It is known as the American system. The main principle with Mr. Gallaudet was to confine himself to a small number of pupils, and even in the few that he had under his charge, being able, by exercising him in describing things for himself, and to discourage the mere learning by rote; and the result was to stimulate the mind of the teacher, as well as of the pupil, in no small degree.

Mr. Gallaudet's exertions were by no means confined to the deaf and dumb asylum. He took an ardent and active interest in the improvement and extension of common schools, and in the raising up of a superior body of teachers, and wrote several pamphlets on the subject. He also strongly advocated the adoption of means of imparting moral and religious training to prisoners; and he was an earnest promoter of the movement for improving the management of the insane. So strongly did he feel on this matter that, though in bad health, he accepted in 1830 the office of chaplain of the State "Retreat for the Insane," at Hartford; where it is stated, "the experience of each successive year has given an increasing usefulness of the usefulness of his labours, and the efficacy of kind moral treatment, and a wise religious influence in the reformation and care of the insane."

He died on the 10th of September, 1851. About twelve months before his death, the good old man, and his colleague M. le Clerc, had the gratification of receiving from the deaconesses of the asylum a silver plate as a testimonial of their gratitude for the many years of service of plate each; and on the death of Gallaudet, his fellow-citizens proposed to erect a monument to his memory, as a mark of their sense of his services; but as soon as their intentions were known, the deaconesses urged that the superior claim to the performance of that duty, and accordingly a handsome and costly monument was erected to his memory at Hartford, at the "sole expense of the deaf-mutes of the United States," the designer and architect of the monument being both deaf and dumb persons.

The publications of Mr. Gallaudet are numerous, but chiefly pamphlets on the education of the deaf and dumb, and on other educational matters; lesson books; and articles in educational periodicals. He also published a volume of sermons, and some books for the young, one of which, "The Child's Book of the Soul," had an extended popularity both in America and in England, and was translated into French, Spanish, Italian, and German.

(Margard, Tribute to Gallaudet, 8vo, Hartford, U.S., 1852.)

GALLE, POINT DE, a town, fort, and harbor on the south coast of the island of Ceylon, 73 miles S. by E. from Colombo, is situated in 6° 1' N., lat., 80° 16' E. long. The site is a beach, and fort was given by a low rocky promontory named the Point de Galle. The harbor, which is the largest point, which extends towards the east, and a piece of land sloping inwards from the west, thus forming a small bay. The entrance to the bay is about a mile wide, but as there are many dangers; viz., rocks and sand-banks, and the risk of the anchorage, which is-although the town in 5 fathoms depth of water. There is a pier; a jetty was constructed in 1847, and a new wharf in 1853. The increase in the number of steam-steamers calling at the port chiefly to take in coal has caused various proposals to be made for improving the harbor, but funds are wanting. The fort, built by the Dutch, is upwards of a mile in circumference, and contains several large and commodious houses inhabited by Europeans. The town, or petlah, inhabited by natives, is extensive, contains many fine houses, and is surrounded by a wall. The schools here maintained by the government for the education of the natives. An iron lighthouse, constructed in London, was erected in 1846; the total height of the light above the sea-level is about 130 feet; the range of its rays is 15 miles, and the letters, d.c., are forwarded immediately to Colombo, whence they are transmitted to all parts of Ceylon. Letters taken by steamers from Point de Galle reach Madras in three days and Calcutta in nine days. Bombay is reached by steamer in 21 days.

GALLOWELLIA [MELSSONIE, S. 2]

GAMBIA COLONY, the British settlements on the Gambia, a river in Western Africa. The source of the Gambia has not been definitely ascertained. According to the most reliable accounts it rises in the country of the Fouta-Jalon, very near and a little to the south of the source of the Rio-Grande, in 10° 36' N. lat., 11° 18' W. long., in a valley surrounded by mountains. The river flows first east and then north till it reaches 12° 25' N. lat., where it turns and flows south to 11° 18' N. lat., where, after having flowed upwards of 400 miles, it is less than 50 miles from its source. Its course is then generally north-west as far as 14° 30' N. lat., 12° 18' W. long, whence it flows westward with many meanders, and then south, and lastly north again, and continues during a course of 600 miles, until it reaches the Atlantic. The Gambia has many affluents, especially in the upper part of its course. The most remarkable on the right bank are the Ra Creek, the Neclabany, the Nyariro, the Nyan-chor, Kaur, Porf, the Jelata, and the Erupina, 45 miles below which the Gambia throws off a considerable branch named the Casmanas, which by numerous channels flows into the St. Domingo. The width between Cape St. Marie and the island of Sangomar is about 25 miles.

The Gambia has been regarded in the past as being of little importance, but it has now been found to be one of the most promising among the African territories as a source of wealth and trade. The trade of the colony has increased upwards of 150 per cent on the value of 1810; and the revenue of the colony has increased from 49,250/. in 1810 to 186,404/, of the imports to 107,011/ in 1852. The exports amounted to 187,556l., the imports to 110,174. The number of vessels arriving at the colony during 1852 was 256, 30,376, of which 31 ships of 2,507 tons were British. The number and tonnage of ships cleared outwards during 1852 were:—Ships 260, tonnage 30,188, of which 30 ships of 4,994 tons were British. The number and tonnage of vessels registered as belonging to the port of Bathurst increased from 24,670 in 1845, to 24,850 in 1852, the principal export in that year being ivory, the quantity being 2,923; above 50 tons 14 vessels, tonnage 1270. Of the amount of exports for 1851 (186,404l.) the article of ground-nuts alone furnished 133,133¢l. value. The quantity of ground-nuts exported in 1850 was 1,500 tons; in 1851 it was 2,500 tons; in 1852 it has risen from 47 tons in 1836, to 11,094 tons in 1851. The ground-nuts are chiefly exported to France. The increased demand for this produce has tended to encourage settled and industrious habits among the native African population, many
of whom travel hundreds of miles from the interior, and hire from the chiefs whose lands lie on the banks of the Gambia, such small portions of ground as their circumstances allow them to cultivate. After the produce of two or three years has enabled them to purchase supplies of European goods, they usually make up parties of from 20 to 100 strong and return to their homes in the interior. These migratory labourers are called 'tillehunks,' or men from the east. The principal establishments of the Gambia Colony are at Bathurst, on the island of St. Mary, the chief river, whence the produce of the country is shipped for England, and at MacCarthy's Island. A colonial steamer has been stationed at Bathurst for some years, and has been of considerable assistance in facilitating communication with MacCarthy's Island, and with trading stations on the banks of the Gambia. The land and sea breezes blow regularly over St. Mary Island for a considerable part of the year. The surface is a low plain with a slight descent on the north and east towards the centre, which during the rainy season is much inundated. The soil is sandy, with a very small admixture of loam. In the shade the thermometer does not rise above 90°. Water is scarce and not of good quality. Bathurst town does not stand upon the curing of river, a mile above, a high, a water-market, and is good and substantial government and public buildings have been erected, as well as numerous handsome and convenient warehouses and dwellings; the remainder of the houses are rude and made of mud. The immediate trade of the island is with about 50, but the number of European and American sailors and others visiting Bathurst every year is little short of 1200. There is a Roman Catholic chapel, capable of accommodating 600 persons, but no suitable place of worship for Protestants. The latter, by and for any time longer than 24 miles in length, and stretches along the shore of the Atlantic, with an elevation above the sea varying from 60 to 90 feet. It is situated near Cape St. Mary, and being intended to be built upon by merchant and others, residents of Bathurst, it has been called Giffen.

The population of Gambia Colony, according to the census taken March 31st 1851 was 6963, as follows, namely:

Of the total population 82 were returned as engaged in agriculture, 330 in manufactures, and 278 in commerce.

MacCarthy's Island, the Janjan Bays of the natives, has an area of about 3 square miles, and is 180 miles from the mouth of the river, following its windings, in a populous district, 60 miles below the falls of Baracundu, np to which spot the river is navigable for vessels of 100 tons burden. Fort George, on the island, is in 15° 29' 25' lat., & 15° 46' W. long. or 20c. 46' 70, and is about 11 miles above the level of the sea, and both are in a great measure covered with water during the rainy season. Tropical remittent fever occurs at both places, but with most intensity at MacCarthy's Island. MacCarthy's Island has a rich alluvial soil, which in the dry season becomes a mass of burnt clay. The thermometer frequently rises to 106° or 108° in the shade.

The Wesleyan Methodists have schools at Bathurst, at MacCarthy's Island, and at Barra opposite Bathurst; the total number of boys and girls attending is no less than 50, and there have a school at Bathurst under the care of several Sisters of Charity.

GAME LAWS. Hares are no longer game, in the sense of its being necessary to take out a certificate to kill them (11 & 12 Vict. c. 29).

GAMING. The numerous alterations which have been made in the law relating to contracts by way of gaming, to gambling-houses, and to betting-offices, call for some repetition of what has been already stated on this subject. (Gaming.) Playing at cards, dice, or other games of chance, merely for recreation, and without any view to inordinate gain, is by the common law considered perfectly innocent. Not so the offence of gaming: which the law looks upon as a tacit confession that the company engaged therein do, in general, exceed the bounds of their respective fortunes; and therefore they cast lots to determine upon whom the ruin shall at present fall, that the rest may be saved a little longer. In this light, it is an offence of the greatest malignity, and the necessary consequence to promote public idleness, theft, and debauchery, among those of a lower class: and among persons of a superior rank, it has frequently been attended with the sudden collapse of ancient and opulent families, an abandoned prostitution of the principal of family and virtue, and too often has ended in self-murder. To restrain this pernicious vice among the inferior sort of people, the statute of 33 Hen. VIII. c. 9, was made; which prohibited all but gentlewomen the games of tennis, tables, cards, dice, bowls, and other unlawful diversions, such as lodging in the fields, slide-thrift, or above-groat, cloysh-cayls, half-bowl, and cotingy, unless in the time of Christmas, under punicanty pains and imprisonments. By the statute 16 Car. II. c. 7, it was enacted, that no gambling or betting lost more than 100l. at one time, he was not compelled to pay the same; and the winner forfeited treble the value, one moiety to the king, the other to the informer. By the statute 12 Geo. II. c. 14, further provided, that all bonds and other securities, given for money lent at the time to play withal, should be utterly void; that all mortgages upon the same consideration, should enure to the use of the heir of the mortgagee; that, if any person at the time of the loan should cry 'stop,' he should forfeit five times the value to any person who used for it, and (in case of cheating) should be deemed infamous, and suffer such corporal punishment as in case of wilful perjury.

The effect of these, and various other statutory provisions, which need not be enumerated, was that all gambling securities, even when transferred to purchasers for a valuable consideration, and without notice of their illegal origin, were altogether void; a result under such circumstances often attended with great hardship and injustice. The law was, however, remedied by the statute 3 Geo. IV. c. 41, by which securities given for considerations arising out of illegal transactions are declared not to be void; but to be deemed as having been given for an illegal consideration only, the object and consideration having been the treble of the principal of such securities. Finally, by the statute 8 & 9 Vict. c. 106, repealing the Act of Hen. VIII. (so far as relates to the prohibition of the games of skill therein mentioned, together with the statutes of Charles II. and Anne, and several others), every person who by any fraud, unlawful device, or ill practice, in playing at or with cards, dice, tables, or other game, or in bearing a part in the stakes, wagers, or adventures, or in betting on the sides or hands of those that play, or in wagering on the event of any game, shall forfeit, p专辑, all of the share of the same, and any sum of money or valuable thing, is guilty of obtaining it by a false pretence, with intent to cheat or defraud; and being convicted thereof, is punishable accordingly. By the same statute all contracts or agreements, by which any sum of money or valuable thing, are declared to be null and void, and no suit is to be maintainable for recovering any money or valuable thing alleged to have been won upon any wager, or deposited in the hands of a stakeholder. This provision, however, does not apply to any money subscribed or contributed for or toward any plate, prize, or sum of money to be awarded to the winner of any lawful game (such as a foot-race or dominoes), sport, pastime, or exercise.

For the suppression of gaming-houses, many statutes have been passed from time to time. The Act 33 Hen. VIII. c. 9, first prohibited the keeping of any gaming-house for profit, under a penalty of 40l. a-day; and subjected any person
hanging and using such gaming-houses to a penalty of 60, 80l. The same statute, and also the statute 30 Geo. II. c. 24, inflicted penalties as well upon the master of a public-house, wherein servants were permitted to game, as upon the servants themselves, who were found to be gaming there. Special provisions for the prevention of this offence were afterwards made by the statute 3 Geo. IV. c. 61, the unlawfully and knowingly permitting of any unlawful game, or any gaming whatever, in a public-house, may involve a forfeiture of the licence as well as a fine, and a licence not also required under a penalty, to be obtained annually, at the general annual licensing meeting of the justices of the peace, by such persons as keep public billiard-tables and bagatelle-boards, or instruments used in any game of a like kind.

The general principle of the reign of George II. was, all private lotteries by tickets, cards, or dice (and particularly the games of faro, basset, ace of hearts, hazard, passage, roolly-polly, and all other games with dice, except back-gammon), are prohibited under a penalty of 200l. for him that shall erect such lotteries, and 50l. a time for the players; and by the statute 42 Geo. III. c. 119, games called little-gets are declared to be common and public nuisances, and a penalty of 500l. is imposed on persons keeping any office or place for the sale of, or for the conducting of any lottery whatsoever, not regularly by public lottery.

Public lotteries, as we have already seen, under the denomination of Parliaments, and all manner of ingenuous devices, under the denomination of sales or otherwise, which in the end were equivalent to lotteries, had been before prohibited by a great variety of petty penalties.

The effect of these statutes being to render all lotteries illegal, whatever might be the object, it was found necessary to pass a special Act for the protection of those laudable associations, generally called Art-Unions, having for their object the promotion of particular arts, and required, accordingly, by the 9 & 10 Vict. c. 48, any voluntary association constituted for the distribution of works of art by lot, is to be deemed legal; provided it be incorporated by charter or by deed constituting the association and its rules be submitted to and approved of by a committee of the Privy Council.

The statute 13 Geo. II. c. 16, to prevent the multiplication of horse-races, another fund of gaming, directed that no plates or matches under 50l. value should be run, upon penalty of 200l. to be paid by the owner of each horse running, and 100l. by such as advertised the plate. But in consequence of a number of vexatious actions having been brought under this statute, it was, so far as it related to horse-racing, repealed by the statute 16 Geo. II. c. 119. The last clause of the section, viz. that the provisions of the statutes 33 H. VIII. c. 9, and 13 Geo. II. c. 19, and of the exception before mentioned in the statutes 8 & 9 Vict. c. 109, is to place all bags relating to horse-racing under the same laws as other bags.

"But," as observed by Blackstone, "particular descriptions will ever be lame and defective, unless all games of mere chance are at once prohibited; the inventions of sharpers being swifter than the punishment of the law, which only hunts them from one device to another." Such contracts as to horse-racing legalised, than an immense number of petty gaming-houses sprung up, under the name of betting-offices. The demoralisation which was found to be the immediate result called for the interference of the legislature, and the statute 16 Geo. II. c. 119, was accordingly passed, expressly for the suppression of these haunts of vice.

Under this Act, the owner or occupier, or any person using such places, may be summarily convicted, and either punished by a fine of 500l. or imprisonment with or without hard labour, for any period not exceeding 14 years. Persons receiving deposits on bets in such houses incur a penalty of 50l., or three months' imprisonment with or without hard labour, for the exhibition of placards or bands-bills, or the display of any sign or other device, under a penalty of 50l., or two months' imprisonment; and summary particulars are conferred on magistrates and constables to enter and search suspected houses.

This only added here, that a bet is not entitled to a certificate, or the certificate if granted is void, if he has lost 20l. in one day or 500l. a year by any sort of gaming or wagering.

**Common gaming-houses are public nuisances,** and the keeper thereof is guilty of an indictable offence. To encourage the prosecution of such pernicious establishments, the statute 30 Geo. II. c. 36, as amended by 58 Geo. III. c. 70, imposes on the overseers of the parish, or the constable, the duty of prosecuting, whenever two rated inhabitants depose before a magistrate to their belief of the fact of the house being a gaming-house, and enter into recognizances to give evidence thereof. The costs of the prosecution are, in this case, allowed out of the rates. In the construction, the two inhabitants who originated the proceeding to be entitled to each 10s. To facilitate such prosecutions, it is expressly provided that the person appearing as acting as master, or as having the care and management of any gaming-house, shall be deemed to have the whole of the house in his keeping, and the offence is punishable by a fine, to which, by the statute 3 Geo. IV. c. 114, imprisonment and hard labour may be added.

The more recent enactments of the statute 8 & 9 Vict. c. 16, and 17 & 18 Vict. c. 93, have still further facilitated the prosecution of this offence. The owner, occupier, or keeper, and every person in any manner conducting the business of any common gaming-house, or advancing or furnishing money for the purpose of gaming, may now be convicted on the oath of one witness, before two justices of the peace; and in addition to the penalties of the Act of Henry the Eighth, be fined in any sum not exceeding 5000l., or in the discretion of the justices, be committed to the house of correction, with or without hard labour, for any period not exceeding 14 years or months. No proceeding under these statutes is a bar to an indictment being preferred; but no person summarily convicted under them can afterwards be proceeded against by indictment for the same offence. To remove any doubts that may have arisen as to the effect of the aforesaid Acts, and other Acts mentioned, the statute expressly provides that any person examined as a witness, either before the justices or on the trial of any indictment or information touching any unlawful gaming, and who shall receive from the court a certificate of his examination or trial, shall be able to prove, in any criminal prosecution, forfeitures, and disabilities in respect of such unlawful gaming, while the second statute expressly enables the justices to require persons apprehended in gaming-houses to appear before them.

Facilities are given by these statutes for entering forcibly houses and rooms suspected to be used as places for gaming; and for the arrest of persons found there; heavy penalties are imposed on persons obstructing the entry of constables, and the fact of such obstruction being itself a felony.

The provisions of the statute 33 H. VIII. c. 9, and 13 Geo. II. c. 19, and of the exception before mentioned in the statutes 8 & 9 Vict. c. 109, is to place all bags relating to horse-racing under the same laws as other bags.

"But," as observed by Blackstone, "particular descriptions will ever be lame and defective, unless all games of mere chance are at once prohibited; the inventions of sharpers being swifter than the punishment of the law, which only hunts them from one device to another." Such contracts as to horse-racing legalised, than an immense number of petty gaming-houses sprung up, under the name of betting-offices. The demoralisation which was found to be the immediate result called for the interference of the legislature, and the statute 16 Geo. II. c. 119, was accordingly passed, expressly for the suppression of these haunts of vice.

Under this Act, the owner or occupier, or any person using such places, may be summarily convicted, and either punished by a fine of 500l. or imprisonment with or without hard labour, for any period not exceeding 14 years. Persons receiving deposits on bets in such houses incur a penalty of 50l., or three months' imprisonment with or without hard labour, for the exhibition of placards or bands-bills, or the display of any sign or other device, under a penalty of 50l., or two months' imprisonment; and summary particulars are conferred on magistrates and constables to enter and search suspected houses.

This only added here, that a bet is not entitled to a certificate, or the certificate if granted is void, if he has lost 20l. in one day or 500l. a year by any sort of gaming or wagering.

**Common gaming-houses are public nuisances,** and the keeper thereof is guilty of an indictable offence. To encourage the prosecution of such pernicious establishments, the statute 30 Geo. II. c. 36, as amended by 58 Geo. III. c. 70, imposes on
GARNISHER. When he had done with it, the judgment debtor is attached to answer the claim of the judgment creditor [ATTACHMENT; ATTACHMENT OF DEBTORS, § 2], the judgment debtor is called the Garnishee, a designation derived from the French garnir (to garnish). The Lord Mayor’s Court of London, the Tolsby Court of Bristol, and the Borough Court of Exeter. The garnishers may be examined as to his indebtedness, he may dispute its liab. or he may pay the debt to the judgment creditor, who can recover by means of a more one if he does so. (Common Law Procedure Act,” 1854.)

GARSTANG. [LANCASHIRE.]

GASES. LIQUIDATION OF. [CHEMISTRY, §§ 1.]

GASTROINTESTINAL GAS. [MEDICINE.]

GAULTHERIA. A genus of plants belonging to the natural order Ericaceae. It has a 5-leaflet or 5-toothed calyx, hypanic at the base, after flowering becoming large and succulent, and covering the capsule with a capsule coating. The corolla is ovate, venicose, with a 5-leaflet revolute border, transparent at the base. There are 10 stamens, inclosed, with filaments; anthers hissed at the apex; lobes biastriate. The hypogynous scales 10, usually united at the base. The ovary half inferior. The capsules 5-seeded, with a loculicidal opening. The species: G. procumbens, Partridge-Berry, Cheesep-Berry, Bohoerry, Mountain-Tea, is found on sterile sand and gravel in mountainous forests in the drier situations in North America. It has a horizontal woody rhizome, often a quarter of an inch in diameter, connected with the roots. The leaves are high, round and somewhat downy. The leaves are scattered near the extremities of the branches, evergreen, coriaceous, shining, oval, or orbata, acute at both ends, revolute at the edge, and furnished with a few small serratures, each terminal by a glandular spot. The flowers are small, white, on a round downy stalks. There are two concave heart-shaped bracts. The calyx is white, clasped into 5 roundish acute segments. The corolla is white, ureolate, 5-angled, contracted at the mouth, the limb divided into 5 short reflexed segments. The flowers are white, ureolate, 5-angled, with a tuft of hairs on a short style. The flowers are white, ureolate, 5-angled, with a tuft of hairs on a short style. The flowers are white, ureolate, 5-angled, with a tuft of hairs on a short style. The flowers are white, ureolate, 5-angled, with a tuft of hairs on a short style.

GAUSS, CARL FRIEDRICH, one of the most celebrated mathematicians of his day, was born at Brunswick, April 22, 1777. He displayed early such marked talent for the abstract sciences, that the Duke of Brunswick, Charles Alexander, took him into his family, and in 1796 he was able to publish a small dissertation on the observation of the planets and asteroids. His dissertation was entitled “Theoria motus corporum celestium,” published at Hamburg, in 4to, in 1809, to which Professor Pauker added, in a separate pamphlet, a geometrical formula, more definitely proving the truth of the principle of the linear triangulation upon which the solutions of which Gauss’s dissertation mostly depended greatly contributed to the succeeding more exact and useful application of the astronomical observations to which, about this time, the attention of the scientific world began to be directed. His “Theoria combinatarum Observationum errorum” was published in 1816, and in 1825, the supplement, issued in 1829. From the same place, was a great addition to scientific knowledge.

On the completion of the Göttingen Observatory, Gauss devoted himself to astronomical observations. On the appointment of the government council, and for applying the Danish admixture of an arc of the meridian to the kingdom of Hanover, he invented the means of making distant stations visible, by reflected sun-light, by an instrument known as the heliometer. Afterwards he was zealously occupied with a discussion of the terrestrial magnetism, for which purpose the government caused a building to be erected for his experiments, near the observatory. By the labours of himself and W. Weber, the science of terrestrial magnetism assumed a new and important phase. The theory was explained by them in conjunction in the Transactions of the Magnetic Union, under the title of “Resultates aus den Beobachtungen des Magnetischen Vereins in Jahre 1836, herausgegeben von C. F. Gauss und Wilhelm Weber” (published by C. F. Gauss, the Magnetic Union volume for 1839, published at Leipzig in 1940, with an “Atlas des Erdmagnetismus, nach den Elementen der Theorie entworfen.” In 1841 he published at Göttingen his “Dioptische Untersuchungen” (“Dioptical Investigations”). This was his latest work on this subject, and was the first essay of a series upon which he published at Göttingen in 1844, under the title of “Untersuchungen über Gegenstände der höhern Geodesie.” In this, with a modest pride, he speaks of the trigonometrical soundings as “partly executed by myself, and partly under my guidance.” This was contributed to the Transactions of the Royal Scientific Society at Göttingen, and appeared in the second volume. He died on February 23, 1855.

We do not attempt to give a complete list of Gauss’s works: he contributed many papers to scientific publications, but the following are among the more interesting that have appeared separately, in addition to those already mentioned:—

GAY-LUSSAC, NICOLAS-FRANÇOIS, was born at St. Leonard, in the department of Haute-Vienne, on December 6th, 1778. He was educated at the Polytechnic School, where his sagacity and talents gained him the friendship of the famous professor of mathematics, Dr. Berthollet. He was appointed to the scientific department of Les Ponts et Chaussées. The expansibility of the gases was at that time a subject exciting much attention; and Gay-Lussac gave the law of dilatation, and showed its constant uniformity. His application to the subject led M. Charles, a scientific physician, to recommend...

GEI

him the use of the balloon, just previously invented, was an excellent means of testing some of his theories, of making fresh experiments, and of at least exciting public attention by such novel means of the pursuit. In connection with M. Biot, he made the proposal to the government; Laplace and Berthelot supported it; and M. Chapital, then Minister of the Interior, gave them the balloon which had been constructed for the use of the police. Furnished with chronometers, thermometers, barometers, hygrometers, electrometers, compasses, and papers and pencils, Messrs. Gay-Lussac and Biot ascended from the garden of the Conservatoire des Arts et des Mâtres on August 19, 1804. Their first ascent, and the air lost 1° of heat for each additional height of 174 metres (180 yards). On this occasion he brought down, in bottles carefully prepared for the purpose, some air from the highest point reached, which on analysis was found to be composed of 75.44 per cent of nitrogen and 24.56 per cent of oxygen. After a voyage of six hours he descended at a village about 61 miles from Rouen.

M. Charles had been correct in supposing these experiments would draw attention to his experiments, and he was introduced to honour, titles, and illustrious friends. Of the society of Arecueil, instituted by Laplace and Berthelot in 1804, consisting at first of only nine members, Gay-Lussac was one. He met Alexander von Humboldt, with whom he was to have a long correspondence, and who showed him the memoirs on which were furnished to the society. In conjunction also with Von Humboldt he endeavoured to determine the position of the magnetic equator, and its interconnection with the terrestrial equator. Gay-Lussac's chief attention however was directed to the Volcanic pile, and the decomposition of acids and alkalies. Napoleon I. had instituted a magnificent prize for the most important discovery made by means of the pile, hoping that it would be gained by one of the members of the Polytechnic School, but when asked to take sides he could not do it, having lost any chance of being able to obtain any grand results. He ordered a colossal one to be constructed immediately, and with it Gay-Lussac and M. Thénard commenced their experiments in 1806.

The result was a work in 2 vols. published in 1811, 'Recherches physico-chimiques sur le pile, sur les acides, sur les acides, l'analyse végétale et animale, &c.' The discoveries, and the improvements on methods of Davy, detailed in this work, were of great importance. In 1816 he was made Professor of Chemistry in the Polytechnic School.

Gay-Lussac's life was one of constant activity. Though he only published two works, and those little more than pamphlets, 'Mémoire sur l'IDEE,' and 'Mémoire sur le Cyanne,' both highly esteemed, he wrote more than a hundred papers on various subjects, and all of great utility. Besides the subjects already mentioned, he wrote on hygrometry, on capillary attraction, on the distinction between oxides and hydrates; and to him is due the discovery of the hydrosulphuric acid, which he first isolated. Some of the very important chemical lectures delivered by him at the Sorbonne, taken down in shorthand, have been published in two volumes.

The merits of Gay-Lussac were not unresented by his country. From 1806, he was repeatedly chosen a member of the Chamber of Deputies, and in 1807 was chosen a representative of the first district of Paris. He was a member of the Academy of Sciences, honorary professor of natural philosophy at the Sorbonne, professor of chemistry at the Jardin du Roi, director of the mint of works in gold and silver, editor (with M. Arago) of the 'Annales de Physique et de Chimie,' with several other official employments connected with the manufacturing industry of France. After a long life of useful labours, and in the enjoyment of excellent health at the age of eighty, he died on May 12, 1850, at Paris, in the mansion provided for him in the Jardin du Roi.

GEDRITE. [MINERALOGY, S.]

GIBRALTAR, [O.]

GIESEKE, [O.]
noble. Mine was a Swedish notion of selflessness, drawn from an imperfect state of society, where the connection between

A periodical works vols., them blameless but "Fnhetstiden", hostile accepted," Iduna, friend, periodicals am Sweden trial ration, journey of sophical his quent Fant, students. bers odicals, childish of in admir ing was his Macbeth appointed to Afzelius Geijer, however in 1844. Geijer put forth, in 1813, a translation of "Macbeth;" and between 1814 and 1816 was associated with Afinancial in the publication of a collection of Swedish popular ballads, "Svenska Folkvisor," in 3 vols., to which however Geijer contributed little more than introductory matter. He had held from 1810, when he was elected during his absence in England, a subordinate post in the University of Upsal, and for some years was in search of a position that would enable him to marry. In 1816 he was appointed professor of history at the University of Upsal, on his retirement; he then married a lady to whom he had been engaged before his journey to England, and in the next year, on the death of Fast, he succeeded to the full professorship. His first lectures had an unexampled popularity, and the lecture-room was crowded, not only with students, but with the best society of Upsal, including ladies. These early lectures were different both in matter and manner from those which his modern colleagues call "expository," but as he grew more profound he became less popular, but he still continued the pride of the university and the favourite of the students. His success with the elegance of Sten Sture had proved his genius, but had not proved the steadfastness he was characterised by the king, who was distressed by his death, and the musical tastes interfered a good deal with his other pursuits, and it was remarked that when he had once got to a pianoforte, it was not easy to get him away from it. He had also frequent leave of absence for the purpose of prosecuting historical researches. One of the most prominent incidents in his academic life was an academic trial to which he was subjected on account of his theological opinions. In an edition which he published about 1820, of the works of Thörner, a Swedish philosophical successor, some passages in the introduction by Geijer, which was entitled, "A Philosophical or Uphilosophical Confession of Faith," were regarded by some of his colleagues as hostile to the doctrine of the Church-Christians, and he was summoned before the ecclesiastical authorities; but a long examination terminated in an acquittal, which wascelebrated as an important triumph of liberty of thought and liberty of the press in Sweden. Geijer's position in the press and in the Church-Christians, I am not a Bible-Christian; I am, so to speak, a Christian on my own account;" and he concludes a statement of his way of thinking in theology with the declaration, "If this is Christianity, I am a Christian." The trial, which he was called to face for the first time, being twice offered a hibiscopic, that on the second occasion being in his native diocese of Carlstad, a distinction the more flattering that in Sweden a bishop must in the first instance be nominated by the clergy. He declined on both occasions. "Perhaps if I accepted," he wrote to a friend, "they might have a harmless middling bishop, but there would be an end to Erik Gustaf Geijer. It is not pride that swells my breast, but an ambition for the time."

For the University of Upsal I am somebody. That would lose more than Wermelund gained." Geijer was in 1839, in a distinguished position as the head of Swedish historical literature. He planned a great history of the country, to supersede that of Dalin and Lagersond, who have been for Sweden what Hume and Smollett have been for England; and it was universally acknowledged that he could have executed a volume of "Svea Rikes Häftor," or "Records of Sweden," promised a masterpiece. Unfortunately, the great work was never carried further. Before proceeding with it the author went to America, and he returned some years later to the same undertaking, having once in 1846, in the Swedish history, the histories of Europe, set on foot by Leo and Uckert; and this was carried before 1843, in three volumes, to the death of Queen Christina, but there it stopped. The professor, in place of continuing it, was occupied in examining the papers of Gustave III, which the king had bequeathed to the University of Upsal, in a chest not to be opened till fifty years after his death. The work was undertaken, by "Konning Gustaf III:s efterlemnade Papper ofversikt och ordning," in 1834, and it was there disappointed the public expectation, but more owing to the insignificance of the royal legacy than to any defectiveness on the part of the editor.

Geijer was not sated with speculations in politics and political economy. Twice he was the representative of the University of Upsal at the diet, and while on the first occasion he was a warm defender of monarchical power, in the second (in 1830) he saw cause to modify his views, and lost the approbation of several of his followers. In 1832 a change of opinion in favour of progress and liberalism, which he avowed and defended in a periodical called 'Litteraturbladet,' written by himself. His views of panerism were developed in 'The Poor Laws and their bearing on Society, or a Series of Political Essays' (published in Upsal, and afterwards published in English (Stockholm, 1840) as well as Swedish, and of which the English version, as it bears to translator's name, and has marks of a foreign hand, may possibly be from his own pen. A dissertation on the history of Sweden during the 'Frihetstiden,' or 'Freedom-Time,' as it is called, which extended from the death of Charles XII. to the revaluation in favour of regal power which was forcibly effected by Gustavus III, is the last of Geijer's works of much importance. The constitution of the liberal, aristocratical government did not pass unquestioned, and were the subject of a controversy with Fryxell. During about thirty years Geijer continued one of the literary magnates of Sweden, in constant intercourse with all that was distinguished in the literary world. His residence in Stockhol and Atterbro, had a correspondence with Frederika Bremer, and wrote both verses and music for Jenny Lind. In 1846 his health began to break, he was obliged to pay a visit to the Schlangenbad of Nassau, and resigned his professorship. He died at Stockholm on the 3rd of April, 1847—a year which was fatal to many of the literary celebrities of Sweden. A collected edition of Geijer's works was commenced soon after his death; but it is still incomplete, though advanced (in 1860) to thirteen octavo volumes. A life by his son, Knut Geijer, is prefixed to the first volume, but before the second sheet had been printed the writer suddenly died. Most of the works of Geijer have been already more or less translated into English. His translation of 'Smollett's Rikes Historia,' of which an English translation by J. H. Turner was published in London, and the first volume of a continuation of which by Carlsson was issued in German, in Leo and Ucker's collection of this period. Many of the volumes of his works were occupied with shorter pieces, articles in periodicals and papers read before the Swedish Academy, of which Geijer became 'One of the Eighteen' in 1824, and was afterwards for some years President. The academical dissertations of Geijer have been collected in two volumes, of which one—in particular on the Swedish colonies in America—are of considerable interest. His letters and his minutes of conversations with Bernadotte, with whom he seems to have been a favourite, were first printed in this collection, and emruse much that is worthy of notice and
preservation, especially when taken in conjunction with his
Minnes, or 'Reminiscences,' perhaps his most attractive
products. The long life of this
finch was left with
finished. It should be observed that Geijer had not only a
taste but a talent for music, and enjoyed some reputation as a
musical composer, a volume of music having been published
in his own handm.sel by

GEINE. [Chemistry, S. 2]

GELATIN. [Tissues, Organic, S. 1]

GENERATIONS, ALTERNATION OF. During the course
of the development of many of the lower animals from
the ovum to their adult condition, they not only pass
through various forms, as is seen in the insect tribes
[Insecta], but at certain stages of their growth they possess
the power of multiplying themselves. The individuals
which exhibit this phenomenon have been called 'nurses,' such
animals being pluripotent. The mode of reproduction in
the mode of reproduction have been called by its first expounder,
Professor Steenstrup, an 'alternation of generations.' This
phenomenon has been particularly observed in the Acephala,
Endea, Polyplegsa, Salpa, and Vorticella. In the various
articles on these families of animals, their mode of develop-
ment is described. As however this subject is one of general
interest, and very imperfectly understood, we take the
opportunity of reproducing here Professor Steenstrup's gen-
eral views on the subject, from a translation of his work
published by the Ray Society:

"The mode of development by means of 'nurses,'
or intermediate generations, is thus seen to be no longer an
isolated phenomenon in nature. The circumstance of an
animal developing itself in a manner more or less distinctly
in its own, but which itself produces a new generation, which
either itself or in its offspring returns to the form of the
parent animal, is a phenomenon not confined to a single
class of lower animals. The vertebrate class is the only one in
which it has not been observed. It would, however, appear
that there is something intrinsic in this mode of
development, and that it occurs as it were with a certain
necessity; on which account it will undoubtedly soon be
recognized in the vertebrata and mankind. It is by no
means to be considered as something paradoxical or ano-
malous (as we have hitherto been too much inclined to deem
both it and the phenomena in which it is exhibited), it must
be in harmony with the rest of development in nature, in
which the fundamental principle of this course of develop-
ment must also be elsewhere expressed, although it may be
displayed in a form under which we shall less readily per-
ceive and recognize it. This is seen when we trace the
mode of development in question more widely through
nature; and whilst considering it not as an isolated view
but also when considered in which it is manifested, we comprehend it in its true
light.

If we collect and regard in one view the whole system of
development exhibited by the individuals of the same
species as are exhibited in the Bell-Shaped Polypes (Clamostoma), the
Claviform Polypes (Coryne), Medusa, Salpa, Vorticella, and
Entosoa, it appears as a peculiar and consequently an
essential feature in this course of development, that the
species (that is, the species in its development) is not wholly
represented in the solitary, full-grown fertile individuals of
both sexes, nor in their development; but that to complete
this representation, supplementary individuals, as it were, of
one or of several preceding generations are requisite. Thus,
the distinction between this course of development and that
which is generally recognised in nature, in which the species
is represented by the individual (of both sexes) and its de-
velopment, is the want on the part of the individuals of a
complete indefinite period, instead of only being represented
by a specific individual, if I may so express it. If I should
agree to regard such an incompleteness in the individual as
the essence of this development, we shall comprehend its
significance in nature when we thoroughly consider this
course of development in various periods, throughout the
above-mentioned families, how it begins and advances, so
that at last we discover to what it tends. I believe, also,
that we might trace even now this development by means of
preparing many generations of 'nurses' in its peculiar
course and advance, as it is described in the foregoing pages,
and the many gaps in the series of observations. Thus we see the greatest incomple-
theses and the highest degree of mutual dependence in the
Comparative course and similar Polypes, in which the generations
representing the unity of the species are very unlike each
other, and in which all the individuals that are used, as it were,
in an outward unity, or into the Polyplegsa, the organic
connection between the individuals and generations is rather more lax;
the perfect geminants or ovigerous individuals are usually quite free, often
even at the same time. While, on the other hand, in the
nurses, and which, in order to the
foundation of a new polypyl stem type. In the Coryne, or clavi-
form Polyplegs, the organic connection between the individuals
and generations is rather more lax; the perfect geminants or
ovigerous individuals are usually quite free, often even
at the same time. While, on the other hand, in the
nurses, and which, in order to the
foundation of a new polypyl stem type. In the Coryne, or clavi-
form Polyplegs, the organic connection between the individuals
and generations is rather more lax; the perfect geminants or
ovigerous individuals are usually quite free, often even
at the same time. While, on the other hand, in the
nurses, and which, in order to the
foundation of a new polypyl stem type. In the Coryne, or clavi-
form Polyplegs, the organic connection between the individuals
and generations is rather more lax; the perfect geminants or
new exhibited, the endeavour to attain something higher is manifest. Each link or generalisation certainly brings its offering nearer to the highest perfection. Accordingly, the aim towards perfection is affected only by means of the 'nursing' by special animals, and is committed to the still and quiet activity of an organ, without the nursing animals there and those being essential to man and not an expression of the will. In all parts of the animal kingdom we see the instances of the still, quiet, and unconscious activity of the animal being developed into voluntary actions, which are undertaken by it from an internal, involuntary action. This is the case in this instance. The development and mode of feeding or nourishing the young, exhibited in its course, of Bees, Wasps, Ants, and Termites, affords a direct example of a mode of which the care of the young is provided for, by the voluntary action of numerous individuals devoted to that object. Those of the young which are to be developed into the more perfect fertile individuals are not protected in the body of the foster-parent, nor is their nourishment secured by one of the organs; both protection and food are afforded them by means which are brought about by the conscious activity of the 'feeders.' The Wasp, for instance, or the Wild Humble-Bee, which has been impregnated in the autumn, and has afterwards sought a shelter to protect itself, begins the nourishment of its offspring in which it builds cells and deposits its eggs. From the eggs proceed larvae, but the insects into which these larvae are metamorphosed, are not fertile; they are barren, and all their faculties are directed to the assisting of the parent. Whether the young of termites to which end some of their external organs are transformed, and to the erection of a better habitation and cells, into which they convey the eggs of the female, and the food of the larvae to be developed from them. Other cells, which continued to be in no case an ovary, and by which numerous progeny of eggs; and again in others, which are more roomy and provided with the best kind of food, but of which there are only a few, is the last brood of the female developed. From the first kind of cells proceed the barren individuals, from the second the males, and from the third the females; after undergoing a metamorphosis, the males and females fly away, impregnation takes place, and the males die; the females however retain, and the whole multitude of barren individuals, which at the same time perform the duty of feeding the young, build cells for their various progeny of eggs, and nourish the three forms of larvae which proceed from them. In this way the inhabitants of the colony become very numerous; nevertheless they all die off in the autumn, and the species propagates the species the year following, under the same development of alternating broods, the earlier of which is always by far the most numerous, and assists in the development of the latter. In the course of Bees, Ants, and Termites, the process of the honey being carried by the individuals which constitute one of those colonies are principally 'feeders,' or individuals which have originated in the precedent divisions of the eggs of the females, and in these is exhibited, even with greater precision, a more marked division of labour in the feeding of the progeny; so that, out of the various precedent divisions, individuals apparently arise which assist in the development of the more perfect progeny in various ways. Thus, there are a hive of bees, individuals which are employed almost wholly in the feeding of the larvae (foragers), whilst others do scarcely anything else than collect wax and build cells (workers). In ant-hills, one set of the feeders is constantly employed in conveying the larvae from one place to another, according as they require the larvae to be brought to the building or the excavations around the habitation. Among the Termites also we are acquainted with several forms of fields which are employed almost wholly in the feeding of the young, but not only by the young of the young, not only by the young of the young, but of the whole community.

Now in the cases in which the more perfect development of the progeny is promoted, either by means of 'nurses' or of 'feeders' (under which latter term we understand special individuals devoted to the actual care or nourishing of the young, which office they fill by a conscious activity), we find that nature has given us a view of the general type of individuals to whose care or life is thus committed the perfecting of a later generation or progeny, consisting of less numerous individuals. This previous or preparatory individuality being essentially different from all previous species, on which account the males of all the animals among which the system of 'nursing' or of 'feeding' obtains, constitute a very subordinate number. That the 'nursing' should be committed to individuals which are as we are acquainted with an organ in them whose natural function would be to perform that office. The generative organs are, indeed, in perfect (female) individuals divided, as it were, into two parts of very distinct natures; the ovary for the preparation of the germ and the production of the egg, and the oviduct and uterus, in which the ova are, as it were, incubated, and the germ and embryo sufficiently developed to allow of its being born. Now, it is actually the case that no true ovary has been discovered in the 'nursing' generative; on the contrary, the female organs, as soon as they are perceptible, are situated in organs which must be regarded as oviducts and uteri, as, for instance, in the most perfect 'nurses' we are acquainted with, the *Aphides.* In the case of those individuals which have remarked that the germes in their earliest condition are collected into an organ at the root of the tail, which may possibly be regarded as a uterus, and that they appear to distend this organ gradually to the size of the whole body. It cannot, however, be accurate so the *Salpa* also show in the most precise way that the associated brood of the *Salpa* does not originate from ova, but that, as germes which are arranged in a definite manner between the walls of a hollow organ, is contained in what can be no case an ovary, and is always produced in a 'germ-tube.' This organ lies in a cavity which may probably be considered very nearly a uterus, which is however always, as it were, a secondary receptacle for the germ; it contains, as it were, an embryo, in the form of individuals which have occupied any previous receptacle or place of formation.

From what we at present know, we may probably assume with some degree of certainty that the 'nursing' individuals are never themselves germipporous, but that they are born with germes in the organs in which the embryos are afterwards nourished; and from all this it appears as if the female generative organism were always divided in those cases in which development by means of 'nurses' occurs, so that as in the more perfect females an ovary especially is formed, so the 'nursing' individuals must have been always presented, in consequence of which, they, as individualised uteri, have assigned to them, as the object of their existence, the performance of the functions of a uterus, and their complete formation must necessarily have been that of the organs which are committed to the fostering of the young. We cannot readily perceive the reason, that because all 'nursing' individuals must be of the female sex, it should follow that all those individuals which feed the young should also be of that sex, and yet this seems to be the case. Anatomy shows us that the 'feeders' amongst bees, wasps, &c., and probably those of all insects living in regular societies, are females, whose sexual organs remain in an undeveloped state. They present scarcely the vestige of an ovary; the uterus is rudimentary, and all propagation consequently in the material way, so to say, is rendered impossible; the imperfection of the organ does not even allow of their acting as 'nurses,' and the propagative instinct in a physical corporeal sense passes into a will for the propagation of the species, into a nerve impelling the feeding individuals to render the necessary amount of these impulsive duties is favoured by the peculiar transformation which some of the organs undergo at the expense of those intended for propagation, in order that they may become more efficient in the performance of their duties. Whether it be, that the development of the species in this case does not take place by means of several generations, but through several broods of the same generation. The reason of the great number of 'feeders,' and for the common good of the colony, we shall accordingly understand the way the fertile individuals scarcely amount to hundreds, may be readily understood when we consider more closely the regular societies of bees and ants, and witness the labour required for the nourishment of the young. But, on the other hand, how the development of the species is promoted by the
multitude of "nursing" animals of which we often see thousands for each single fertile one, appears to us difficult of explanation, since, even all of them can only be regarded as animals which do not appear to differ from others in any other. It does not however seem to me improbable that even the Aphides, trematode mares, and other parasites, which are so immediately injurious to the organisms upon which they live, are not destined merely to promote the extension of the species, but that they also induce in the organisms themselves conditions necessarily more and more favourable to a later generation; plants also and animals afford us many instances that to a certain abundance of parasites there usually succeeds a complete overflow of them.

"I conclude with the remark that, insomuch as in the system of 'nursing' the whole advancement of the welfare of the young is effected only by a still and peaceful organic action, it is not unlikely that the whole of the vital life of the individual, so also all those forms of animals in whose development the 'nursing' system obtains, actually remind us of the propagation and vital cycle of plants. For it is peculiar to plants, and, as it were, their special characteristic, that the germ, the primordial individual in the vegetation or seed, is competent to produce individuals which are again capable of producing seeds or individuals of the primary form or to that which the plant owed its origin, only by the immediate union of its generative products. Unlike this, the great triumph of Morphology, that it is able to show how the plant or tree (that colony of individuals arranged in accordance with a simple vegetative principle or fundamental law) unfolds itself, through a frequently long succession of generations, into the multitude of beings, becomes more perfect, until, after the immediately preceding generation, it appears as calyx and corolla, with perfect male and female individuals, stamens, and pistil (so that even in the vegetable kingdom the greater hermaphroditism does not obtain, which is still supposed to take place in the animal); and after, the fructification brings forth seed, which again goes through the same course. It is this great and significant resemblance to the vegetable kingdom, which in my opinion is, I think, a proof of the identity of generation, and all to which I have alluded in the preceding Essay: I might almost say that the condition of continued dependence incidental to the animal life, is to a certain extent one of less perfection that that which is presented in the progressive elevation in development effected by the agency of the vegetative life."'

GENTIANINE. [CHEMISTRY, S. 2.]

GEOGRAPHY. [MINERALOGY, S. 23.]

GERARD, ENCOMIUM ET ETYMOLOGIE, COMTE, Marshal of France, was a native of Davilliers, in the department of the Meuse, and was born April 4, 1773. He entered the army as a volunteer in 1791, and first saw fire under Jourdan, at Fleurus. He was already a captain in 1799, and Bernadotte, who commanded in the north, saw him in action soon after one of his aides-de-camp. After the treaty of Campo Formio, he attended that general in his embassy to Vienna, and having saved his life during a riot stimulated by the Austrian police, a lasting friendship was established between them. In 1799 he became a chef-d'escadron; and at the battle of Amelotis (Dec. 2, 1800) his good conduct was so conspicuous that he received the Cross of the Legion of Honour on the field.

In 1806 Gerard was appointed to a brigade; and in 1809, at the battle of Wagram, Bernadotte gave him the command of the Saxon cavalry. He next went to serve in Spain, where he continued until October 1811, having been present at the battle of Albuera and several of the important actions of Marshal Macdonald: he was present at the battle of Bailen, and his exertions, which were made on the impulse of the moment and without orders, accelerated the victory. He charged the battery and bayoneted the officers (or rather contrary to orders at Goldberg, and rout the Prussians with great slaughter, for which feat of arms the emperor gave him the command of the 11th corps. General Gerard was several times injured at the battle of Leipzig, October 16, 1813. During the defence of the French territory in 1814, his zeal and intrepidity were frequently commended by Napoleon, especially at the victory of Montees.

After his return from Elba, in 1816, the Emperor gave him the command of the 2nd cavalry corps, and at the battle of the 18th of June he was under the orders of Marshal Grouchy at Waterloo, and when the report of the cannon was heard proceeding from the forest of the Soignes, Gerard recommended an immediate advance of Grouchy's army of reserve to support him.

On the return of Louis XVIII, Gerard retired to Belgium, where in 1816 he married the daughter of General Valence. The following year he was permitted to return to France. In 1830 Louis Philippe appointed him minister of war, but his health compelled him to resign this office a few months later. In 1832 he was sent to besiege the fortress of Antwerp, defended by the Dutch general Chasse, when, having compelled the garrison to capitulate after a gallant defence, he returned to France and was made a peer. In 1834 the citizen king made him president of the council, or prime minister; but his declining health obliged him to resign this office on the 26th of October, after which he withdrew into private life. It is certified that on February 14, 1849, raised Marshal Gerard to the function of Grand Chancellor of the Legion of Honour. The Marshal lived to see the restoration of the Bourbons. He died at Paris, August 17, 1852, and was interred in the chapel of the basilica of the Madeleine. Thus he lived in the utmost mental and moral perfection, and at the age of 108 years, the eldest marshal of France who has ever lived, while he enjoyed the last moments of life, during the night of the 21st of December, 1852. Among his principal works was a commentary on his maps (or geographical atlas) of France, published in 4 folio volumes, 48 plates in mezzotint and 36 plates in lithographic wood engraving. Another atlas of France, with 44 plates in mezzotint, was published in 1824, with a commentary in English, French, and Latin. He also published a commentary on the maps of Spain and India, and a commentary on the maps of the World. He published also a commentary on the maps of the Moselle, in 1845. Among his other works was a commentary on the maps of the Seine, published in 1849. He also published a commentary on the maps of the Moselle, in 1845. Among his other works was a commentary on the maps of the Moselle, in 1845. Among his other works was a commentary on the maps of the Moselle, in 1845. Among his other works was a commentary on the maps of the Moselle, in 1845. Among his other works was a commentary on the maps of the Moselle, in 1845.
GEYSERS. This name is applied to a series of intermittent hot-springs, situated in the south-western division of Iceland. A hundred and one of them are said to break out within a circuit of two miles. These springs are evidently connected with the volcanic phenomena which so remarkably characterise the whole district of Iceland. A recent investigator of the eruptive phenomena of Iceland thus describes its activity. "The surface of the Iceland slopes gradually from the coast towards the centre, where the general level is about 3000 feet above the surface of the sea. On this, as a pedestal, are planted the Jökull, or Ice Mountains of the region, which extend both ways in a north-south direction. Along this chain the active volcanoes of the island are encountered, and in the same general direction the thermal springs occur, thus suggesting a common origin for them and the volcanoes. From the ridges and chasms which divide from the mountains mighty masses of steam are observed to issue at intervals, hissing and roaring, and where the escape takes place at the mouth of a cavern, and the resonance of the cave lends its aid, the sound is like that of thunder. Lower down in the valleys is observed that it is continued in a thin vapour, a repulsive blue-black ammoniacal Pence is balled, rising at times into huge bladders, which on bursting scatter their slimy spray to a height of 15 or 20 feet. From the base of the hills upwards extend the gushing springs, the shallow-fields which crown the summits. From the arches and fissures of the glaciers vast masses of water issue, falling at times in cascades over walls of ice, and spreading for miles and miles over the country. Excessive morasses and springs are thus formed, which lend their inoffensive monotony to the dismal scene already before the traveller's eye. Intercepted by the cracks and fissures of the land a portion of these waters is conducted to the hot rocks underneath; here, mere water, the water, hot springs, are produced. Where the ground regions, both travel together, to issue at the first convenient opportunity either as an eruption of steam or as a boiling spring."

The origin of the water which feeds the springs is here hinted at. That origin is atmospheric. The summits of the Jökull arrest and mix the clouds, and thus cause an extraordinary deposition of snow and rain. This snow and rain constitute the source from which the springs are fed. The Jökull, the snowmelt, the air, these are the main factors every spring, exactly as we find them in rain water, furnish the proof of this; for the known deportment of these substances preclude them from being regarded as real volcanic products."

The springs which feed the Geysers, and which are poured out from them again boiling, probably take their rise in Mount Hecla, the summit of which is not more than 30 miles from the Geysier district. It is here that the rushing water is sometimes heard in chasms beneath the surface, and it has more than once happened that after earthquakes some of the boiling fountains have increased or diminished in violence and volume, or entirely ceased, or that new ones have made their appearance. The phenomena of the Geysers of Iceland have for a length of time arrested the attention of naturalists, and many explanations of them have been given. No one has however so successfully investigated the subject as Professor Bunsen, of Giessen. A summary of these views, with experimental observations, were presented to the Royal Institution by Professor Tyndall in June 1853. After referring to the general eruptive phenomena of Iceland, he described the Great Geysier."

"We have here," he says, "a tube 10 feet wide and 70 feet deep; it expands at its summit into a basin, which from north to south measures 52 feet across, and in the perpendicular distance 60 feet. The interior of the tube and basin is covered with a beautiful smooth plaster, so hard and close as to make it impossible that anything but that presents itself, as how was this wonderful tube constructed? How was this perfect plaster laid on? A glance at the constitution of the geyser water will perhaps furnish the first surmise. In 1000 parts of the water the following constituents are found—

"The lining of the tube is silica, evidently derived from the water; and hence the conjecture may arise that the water deposited the substance against the sides of the tube and basin; but further examination, and especially the deposition of the tube cooled down to the freezing point. It may be bottled up and kept for years as clear as crystal, and without the slightest precipitate. A specimen brought from Iceland and analysed in this institution was found perfectly free from sediment. Further, we must consider that in this way would imply that we took it for granted that the shaft was made by some foreign agency, and that the spring merely lined it. A painting of the Geyser, the property of Sir Henry Holland—himself a witness of these wonderful phenomena—was exhibited. The painting, from a sketch taken on the spot, might be relied on. We find here that the basin rests on the summit of a mound; this mound is about 40 feet in height, and a glance at it is sufficient to show that it is strongly erected by the Geyser. But in building the mound the spring must also have formed the tube which perforates the mound; and thus we learn that the Geyser is the architect of its own tube. If we place a quantity of the geyser water in the basin the following takes place—In the centre the fluid begins to bubble; the next takes place here; the edges where it is drawn up the sides of the basin by capillary attraction, and thus subjected to a quick evaporation, we find silica deposited; round the edge we find a ring of silica thus laid on, and not until the evaporating is continued for a considerable time do we find the slightest turbidity in the central portions of the water. This experiment is the microscopic representative, if the term be permitted, of nature's operations in Iceland. Imagine the case of a simple thermal spring, but one in a basin which is kept at a temperature of 100 feet, and with a gentle incline; the water thus exposed evaporates speedily, and silica is deposited. This deposit gradually elevates the side over which the water passes, until finally the latter has to choose another course; the same takes place here, but until the ground becomes elevated by the deposit as before, and the spring has to go forward thus it is compelled to travel round and round, discharging its silica and deepening the shaft in which it dwells, until finally, in the course of centuries, a column is raised which has so long puzzeled and astonished both the traveller and the philosopher."

"Before an eruption the water fills both the tube and basin; detonations are heard at intervals, and after the detonation a violent outburst occurs; the column of water in the pipe appears to be uplifted, thus forming a conical eminence in the centre of the basin, and causing the water to flow over its rim. The detonations are evidently due to the production of steam in the subterraneous depths, which, rising into the cooler water of the tube, becomes condensed and produces explosions similar to those produced on a small scale when a flask of water is heated to boiling. Between the interval of two eruptions the temperature of the water in the tube towards the centre and bottom gradually increases. Bunsen succeeded in determining its temperature a few minutes before a great eruption took place; and these observations furnished to his clear intellect the key of the phenomena. A little below where the water was within two degrees of its boiling point, that is, within two degrees of the point at which water boils under a pressure equal to that of an atmosphere, plus the pressure of the superincumbent column of water. The actual temperature at 20 feet below the bottom was at a fixed six feet by the generation of a mass of vapour below. The liquid spreads out in the
basin, overflows its rim, in time the elevated section has six feet above the lowest one upon its surface. A boiling point under this diminished pressure is 191°C; hence in its new position its actual temperature (192°C) is a degree above the boiling point. This excess is at once applied to the generation of steam; the column is lifted higher, and its pressure further lessened; more steam is driven off; and thus, after a few convulsive efforts, the water is ejected with immense velocity, and we have the geyser eruption in all its grandeur. By its contact with the atmosphere the water is cooled, falls back into the basin, sinks into the tube through which it originally ascended, and fills the basin again.

The detonations are heard at intervals, and ebullitions are observed; but not until the temperature of the water in the tube has once more nearly attained its boiling point, and the lifting of the column able to produce an eruption.

"In the regularly-formed tube the water nowhere quite attains the boiling point. In the canals which feed the tube, the steam which causes the detonation and lifting of the column must therefore be formed. These canals are in fact nothing more than the irregular continuation of the tube itself. The tube is therefore the sole and sufficient cause of the eruptions. Its sufficiency was experimentally shown during the lecture. A tube of galvanised iron six feet long was sunk into the earth in a field near the University, and one near its centre to imitate the lateral heating of the geyser tube. At intervals of five or six minutes throughout the lecture eruptions took place; the water was discharged into the tube, which was then filled back into the basin called the tube, became heated again, and was discharged as before.

"Sir George Mackenzie, it is well known, was the first to introduce the idea of a subterranean cavern to account for the phenomena of the Geyser. His hypothesis met with general acceptance, and it is even possible that some of those who accompanied Bunsen to Iceland. It is unnecessary to introduce the solid objections which might be urged against this hypothesis, for the tube being proved sufficient, the hypothetical cavern disappears with the hypothesis which required it.

"From the central portions of the geyser tube downwards, the water has stored up an amount of heat capable, when liberated, of exerting an immense mechanical force. By an easy calculation it might be shown that the heat thus stored up could generate, under ordinary atmospheric pressure, a column of steam having a section equal to that of the tube and a height of nearly 1300 yards. This enormous force is brought into action by the lifting of the column and the descending water, which is stirred up by the eruption of ashes. A moment's reflection will suggest to us that there must be a limit to the operations of the Geyser. When the tube has reached such an altitude that the water in the depths below can no longer communicate pressure, cannot attain its boiling point, the eruptions of the water cease. Yet when pressure is thus released, the water, however continues to deposit its silica and forms a 'lang,' or cistern. Some of those in Iceland are of a depth of 30 or 40 feet. Their beauty is indescribable; over the surface a light vapour curls. In the depths the steam is a bluish white, and tints with its own has the fantastic incrustations on the cistern walls; while at the bottom is observed the month of the once mighty Geyser. There are in Iceland traces of vast, but now extinct, geyser operations. Mounds are observed whose shafts are filled with rubbish, the walls having forced a way underneath, and retired to other scenes of action. We have in fact the Geyser in its youth, manhood, old age, and death, here presented to us—in its youth as a mere wave; in its manhood, as a fully-drilled, stately cistern; in its old age as the tranquil tube, while its death is being marked by the ruined shaft and mound, which testify the fact of its once active existence.

"Next to the Great Geyser the Strokkur is the most famous eruption of Iceland, and is situated not far from the town of Haukadal. It is not however cylindrical like that of the Geyser, but funnel-shaped. At the mouth it is 8 feet in diameter, but it diminishes gradually, until near the centre the diameter is only 1 foot. By long stones and pebb into the tube and thus stopping it, eruptions of water are produced. The "inches of height often exceed those of the Great Geyser. Its action was illustrated experimentally in the lecture, by stopping the galvanised iron tube before allowed to locally with a cork. A jet of water was forced up and the pent-up heat converting itself suddenly into steam, the water was ejected to a considerable height—thus demonstrating that in the tube the alone is the sufficient cause of the phenomenon." ('Proceedings of Royal Institution.')

The results of the researches of Professor Bunsen on the Geyser of Iceland seem to throw great and unexpected light on the phenomena of volcanoes. Sir Charles Lyell closes his account of Bunsen's researches with the following remarks:

"In speculating therefore on the mechanism of an ordinary volcanic eruption, we may suppose that large subterranean cavities exist at the depth of some miles below the surface of the earth, in which molten lava is stored, and by heat and pressure of the air contained into these, the steam thus generated may press upon the lava and force it up the duct of a volcano, in the same manner as a column of water is driven up the pipe of a Geyser. In other cases eruption takes place by a continuous flood of molten lava, accompanied with red-hot water (for water may exist in that state, as Professor Bunsen reminds us, under pressure), and this column may have a temperature regularly increasing downwards. A disturbance of equilibrium may first bring on an eruption near the surface, by the expansion and conversion into gas of entangled water and other constituents of what we call lava, so as to occasion a diminution of pressure. More steam would then be liberated, carrying up with it jets of melted rock, which being hurled up into the air may fall in the form of ashes or ash-cinders. This is naturally followed by the arrival of lava and water more and more heated at the orifice of the duct or crater of the volcano, expansive power may be acquired sufficient to expel a massive current of lava. After a period of time long sufficient for the quiescence succeeds, during which fresh ascensions of heat are communicated from below, and additional masses of rock fused by degrees, while at the same time atmospheric or steam-water is descending from the surface. At length the conditions which are necessary to cause a renewed eruption returns in that place, the cycle of similar changes is renewed." ('Principles of Geology,' p. 565.)

GIGANTOLITE. [Mineralogy, 8.1.]
GIIBERTUITE. [Mineralogy, 8.1.]
GIOBERTI, VINCENZO, was born on the 5th of April 1801, in the city of Torino (Turin), the capital of the kingdom of Sardinia. He studied with a view to the ecclesiastical profession, and having completed his education in the University of Turin, received the degree of Doctor of Theology, and became one of the teachers in the theological college. Soon after the accession, in 1831, of Charles-Albert to the throne of Sardinia, Gioberti was appointed chaplain to the king, and continued to perform the duties of that office till 1833, when, on some accusation or suspicion of being implicated in the political agitations then prevailing in various parts of Italy, he was suddenly seized in the apartments which he occupied in the palace, and imprisoned in the citadel, where he was kept for several months under the pretence of being held at liberty on the condition that he quit the country as an exile. He went to Paris, where he resided till the end of 1836, when he removed to Brussels, having accepted the offer of a situation as teacher in one of the public colleges. Gioberti wrote at Brussels, during his long abode there as an exile, nearly all those works which not only extended his literary reputation throughout the whole of Europe, but procured that enthusiasm of admiration which was displayed by the Italians after his return to his native country. The first of these works was the 'Teoria del Sovrannaturale, o Discorso sulle Convenienze della Religione Rivelata con il Progresso Civile delle Nazioni,' 1837. His next work was the 'Introduzione alla Storia Politica,' 1838, and the 'Lettere intorno agli Errori Filosofici di Antonio Rosmini,' 3 vols., 1840-41; and the two treatises 'Del Bello,' 1840, and 'Del Bello,' 1843. His 'Pramato Morale e Civile degli Italiani,' 1845, was read with eagerness in every part of Italy, and the criticisms of them of the publication of that unfortunate country, which, with the sole exception of the Sardinian kingdom, have not hitherto been realised. There was to be a confederation of the Italian states, in which the faithful would perish, the nation, which was not to drink the cup of salvation, and the monks and Jesuits, were all to play their part. The states were to be reformed, and popular rights and privileges gradually established. The pope was to be the religious head of the confederation, and Rome the capital of the Empire: King of the peasants, and the king of Turin the grand cedzar. The Jesuits alone were disapproved, and Gioberti
attached them in his "Prolegomeni," 8vo, 1843. In 1848,
he ascended to the pinnacle of his career in 1848, adopted the views of
Gioberti, and began to carry out the reforms recommended in "Il Primato;" and as the opposition of the Jesuits still con-
tinued, Gioberti produced his great attack on their principles and
practices, under the title of "Il Gesùsita Moderno," 5 vols.
8vo. 1847.
When the French revolution of February 1848, occurred,
Gioberti was at Paris occupied with his plans for the renova-
tion of Italy. On the 20th of April he quitted Paris, after an
exile of fifteen years, to return to his native city of Turin,
whence his escape was welcomed by a display of banners in
day, and illuminations and fireworks at night, accompanied with
music and dancing and patriotic songs; and afterwards when he passed through Milan, Genoa, Florence, Rome, and
other cities, he was everywhere received with the greatest
enthusiasm, so that his journey resembled a triumphal pro-
cession.
On his return to Turin he was elected a member of the
chamber of deputies, of which he was unanimously chosen
president. He was opposed to all violent reforms, but the tide
of political excitement in the year 1848 threw him into the
ranks of the opposition, and on the 16th of December the
king appointed him the prime minister of a democratic
administration. He soon found himself to be in a false position,
and the difference of opinion between himself and the
ministers, who were largely inspired by Caracciolo, brought
on February 1849. He was succeeded by Pinelli, and soon after-wards was sent to Paris to solicit aid from the French govern-
ment in the approaching contest with Austria. His mission
was of short duration: Charles-Albert defeated at Novara, and Victor-Emmanuel II. has, alone, of all the rulers of Italy, preserved for his subjects a constitutional government, a free press, and a just adminis-
tration of the laws. Gioberti remained in Paris, and the fruit
of his political labours was, in 1851, "Memorie sulla forza
Civile d'Italia," 2 vols. 8vo, 1851. He died October 26, 1862,
in Paris.

GIARDAI, MADAME DELPHINE DE, the wife of
Emile Giaradin, and daughter of Sophie Gay, a literary lady of
reputation, well known in the literary world from the begin-
ning of the 19th century. She was what is called a precocious genius, and at the age of fourteen was noted for her remarkable beauty. In 1833 a poetical elegy of hers, containing all the illustrious names of the day, was honourably mentioned by the French Academy. On the 20th of April 1848, she was received with great
enthusiasm in the Capitol of Rome by the Académie du Trône, as one of their members. She received a more flattering ovation in Paris, on her return. The artist Legros, who had recently completed the new frescoes in the church of Madie. Delphine Gay to a place of honour beneath the dome, whence she recited some of her own poems in the presence of a brilliant assembly. As soon as she finished a shower of wreaths and bouquets were thrown at her feet. King Charles X. and Legros, in person, collected the petals of the roses. Shortly after, she met with M. Emile de Giaradin, to whom she was married in 1831.

Immediately after this union Madame de Giaradin engaged in
a variety of literary undertakings, producing novels, romances, and
fugitive poems for the booksellers; tragedies, comedies, and
vaudevilles for the theatres; and feuilletons for the
newspapers. Her charming "Leçons Parisiennes" appeared in the journal "Le Presse," under the name of "Vau de G.," by Mlle. Legros. Her novel, "La Reine," was recommended by Radcliffe, and another,
"Le Carné de M. de Balzac," 1838; "L'Ecole des Journalistes," a five-act comedy, 1840; "Judith," a tragedy, 1842; "Cléopâtre," a tragedy, 1847; "Lady Tartuffe," a comedy which produced much sensation, 1849; and "La Jeste,
Sainz," 1847.

GIADOLUS, Cerc-Flag from 'gladius,' a sword, refer-
ring to the shape of the leaves), a genus of plants belonging to the natural order Rosaceae. It has a tubular 2-lobed corolla; several petaloid petals arranged in a spiral; and seeds with an aril; root a coated bulb; leaves en cauliform, sheathing. The species in the gardens are bulbous, and are chiefly brought from the Cape of Good Hope.

G. sepium has about 3 flowers in one row; the anthers much shorter than the filaments. It is found in the
mountains of Carcass.

G. polisporus has 3 or 4 flowers, second; the tube twice as
long as the seed-vessel; the oval of the division curved
and remote; the lobes of the stigma papilloso-ciliate
almost from the base; anthers shorter than the filaments;
auricles at the base obtuse, parallel; capsules oblong,
ovate, rounded at the top, marked with six equal furrows.
It is found in Germany.

G. gummosea has second flowers; the filaments half
as long again as the anthers; the base of the division parallel; the tube half as long again as the genus; the lobes of the stigma gradually broader upwards, papilloso-ciliate
almost from the base; capsules 3-edged, ovate, impressed
with six equal furrows; it is found near Buxton and
Frankfort-on-Oder.

G. Illirica has second flowers; the tube three times as
long as the genus; division of stigma linear from the base
to the middle, and with a smooth margin suddenly enlarged
at the top; the capsule 3-edged; it is a native of Illyria.

G. infestus has a lax spike; flowers 4 to 14, obliquely
alternate; division of corolla alternately pink and purple;
uppermost very broad, covering the 3 lateral ones, the 3
lower unequal; anthers shorter than the filaments; seeds globose, prolonged downwards. It is a native of Sicily.

G. Bynanthus has numerous flowers in two rows; the upper
segment of the corolla covered by the lateral ones;
the 3 inferior petals the largest; the anthers longer than the filaments; seeds winged; leaves long,
entiform, and linear. Found in Sicily.

GLAND, a term applied to cells and collections of cells in
the animal body, which have the power of absorbing or
secreting substances. These cells are generally separated from
the circulating fluid. In one sense all the cells of the animal
act as glands; for they separate from the blood the peculiar
substances of which they are composed. The term gland however is only strictly applied to special forms of tissues which separate peculiar matters. "A true gland," says Dr. Carpeiser, "may be said to consist of a
clustered collection of follicles, all of which open into a
common channel, by which the product of the glandular
activity is collected and delivered. The follicles contain
the secreting cells in their cavities, whilst their exterior is in
contact with a network of bloodvessels from which the cells
draw the materials of their growth and development.

In a wider sense however the term gland has been applied
to those parts of the body which are engaged in the
work of generating and absorbing the food or carrying to the blood the materials of used-up
materials. [Ammonit.] In all cases the cell is an active
agent with the power of absorption or secretion. The agency of the gland in the body is seen in the way in which the chyle is
forested from the intestine and glands.

For further investigations on the structure of Glands, see
Tissier, "Omnino, S. 1., pp. 643, 643, 644. After describing the
development of glandular tissue, Professor Goodwin
concisely expresses his views on this subject with the following
remarks:

"It appears to be highly probable therefore that a gland
is originally a mass of nucleated cells, the progeny of one or
more parent cells; that the membrane in connection with the
embryo gland may ever; may, notwithstanding the case,
send a portion of the membranes in the form of hollow cones.
into the masses; but whether this happens or not, the
extremities of the ducts are formed as closed vesicles, and
through these they are for a time formed with the
parents of the epithelium cells of the perfect organ. Dr.
Allen Thomson has ascertained that the follicles of the
stomach and large intestines are originally closed vesicles.
This would appear to show that a cellular organ is the
original form of the gland, and the ducts the part of the
generative spot, which plays so important a part in its future
actions. The ducts of glands are therefore intercellular
passages. This is an important consideration, inasmuch as it
ranges the organology of the intercellular passages and
secreting receptacles of vegetables.

"Since the publication of my paper on the secreting
structures, in the "Transactions of the Royal Society of
Edinburgh," in 1844, I have satisfied myself that I was
erroneously in my supposition that the entire mass of the
cell-wall is opposed to the cavity into which the
secretion is cast. This accords with that most important
observation of Dr. Martin Barry on the function of the
nucleus in cellular development. I have also had an
opportunity of observing this, and to this result I add, at
the time fully anticipate—the remarkable vital properties
of the third order of secretion referred to in the memoir to
which I have just alluded. The distinctive character of
secretions of the third order is, that when thrown into the
cavity of the gland, they consist of ordinary cells, instead of
being the result of partial or entire dissolution of the
secreting cells. It is the most remarkable peculiarity of
this order of secretions, that, after the secreting cells have
been cast into the duct of the cavity, and no longer a
component part of the organism, they retain so much individuality of life as to
proceed in their development to a greater or less extent in their
course along the canal or duct; when they arrive at their
full extent of elimination. The most remarkable instance of
this peculiarity of secretions of this order is that discovered
by my brother. He has observed that the seminal secretion
of the decapods crustaceans undergoes successive develop-
mental changes in the duct of the body, and only becomes
developed into spermatozoa after coitus, and in the
spermatheca of the female. He has also ascertained that,
apparently for the nourishment of the component cells of a
secretion of this kind, a quantity of albuminous matter floats
around the cells which undergo development after separation from the walls of the gland.
This albuminous matter he compares to the substance which,
according to Dr. Martin Barry's researches, results from
the solution of certain cells of a brood, and affords nourishment to
their survivors. In one of other instances in which
cells do not derive their nourishment from the blood but
from parts in their neighbourhood which have undergone
solution, and it involves a principle which serves to explain
many processes in health and disease.

"I conclude therefore, from the observations which I
have made, 1st, that all the true secretions are formed or
secreted by a vital action of the nucleated cell, and that
they are first contained in the cavity of that cell; and, that
growth and secretion are identical—the same vital process
under different circumstances."

Having thus examined the nature of the process by which
the cell secretes, we may now refer to some of the more
prominent modifications of the organs called glands. The
simplest condition of a Gland is a solid mass, the secreting
membrane cast a follicle. These occur in the
skin, as in the sebaceous follicles, and also in the mucous
membrane of the stomach, where they are called gastric
follicles. The stomach occurs in the skin in the sub-epidermal
membrane covered with secreting cells. In the early stages of
the development of all glands we have this simple condition,
and in the permanent condition of the more complicated
glands, when occurring in the lower animals, we have the
same simple development. Thus the laries in some of the
Polyopes and lower Mollusae consists merely of a series of
separate follicles placed in the walls of the stomach. The
chick whilst in the egg presents the same condition of this
organ. The same principle is manifest in the development of a mammary gland in the Female.
The Ornithorhynchus this organ consists of a mere cluster
of blind sacs. In the same way many fishes the pancreas
begins its existence as a mere group of blind follicles.
The pancreas in the common carp is composed of a number of
follicles open into a single tube. Such a condition of the
organ is seen in what are called the Meibomian glands of the
eye. The larger glands of the body, as the pancreas, liver,
and spleen, pass through complicated stages of this
process. Innumerable follicles empty themselves into tubes
which again empty themselves into other tubes until the
whole contents of the gland are thrown out from some
common outlet.

GLAHORN, BRIGG. [Lincolnshire.]

GLAPHYRIA, a genus of plants belonging to the natural
order Myrtaceae. The limb of the calyx is 6-lobed, petals 5,
year 5-celled, many seeded; seeds fixed to the axis, 2 rows
in each cell. The species are small and rare; the annual
petals and cells of ovary 6 or 8 in number.

GLAUCINE. [Chemistry, S. 2.]

GLAD. (M. F. P.)

GLECHOMA. [Wat. S. 1.]

GLADIUM. [Chemist., S. 1.]

GLOBE-FISH. [Tetrodon.]

GLOBE-FLOWER. [Trollius.]

GLOIOSCLADIA, a sub-order of Sea-Weeds belonging
to the natural order Cryptonemiae. The fronds are loosely
gelatinous, the filaments of which they are composed lying
apart from one another, surrounded by a copious gelatin.
The favaellids are immersed among the filaments of the
periphery. It embraces the following genera:

Cruria.—Frond crustaceous, skin-like.

Noccaea.—Frond frilliform, solid, cellular; the ramuli only
composed of 2 to 3 cells, appressed

Glosotiphina. Frond tubular, hollow, the walls of
the tube composed of radiating filaments.

Nemalos. Frond frilliform, solid, elastic, filamentous;
the axis composed of closely packed filaments, the periphery
of the axis cambial, the ramuli elastic.

Doudremontia. Frond frilliform, solid, gelatinous, filamentous;
the axis composed of a net-work of anastomosing filaments;
the periphery of moniliform free filaments.

Cosmetia.—Frond frilliform, consisting of a pointed
filament, whorled at the points; minute minutifilament gelatinous
ramuli.

(Harvey, British Sea-Weeds.)

GLOSSOP, Derbyshire, a manufacturing town and the
seat of a Poor-Law Union in the parish of Glossop, is
situated on elevated ground rising from a deep valley near the
northern boundary of the county, in 53° 26' N. lat., 1° 55' W.
long; distant 49 miles N.W. by N. from Derby, 176 miles
N.W. by N. from London by road, and 193 miles by
the Great Northern and Manchester railway. The
population of the township of Glossop in 1851 was 5497;
that of the entire parish, which contains 49,960 acres,
and is the most extensive in the county, and
one of the most extensive in England, was 56,935.
The town is divided into two distinct districts, that of
Litchfield. Glossop Poor-Law Union contains 10 town-
ships and hamlets, forming a part of Glossop parish, with
an area of 30,707 acres and a population in 1851 of 19,560.

Of the larger towns, there are chapels for Independents and other Dissenters. A charity for
clothing 34 poor men and women was founded by Joseph Hugues, Esq. There is a savings bank. Molandra Castle, although Armadillo Castle in the town, is the site of a Roman station; the works appear to have been nearly square, 366 feet by 336 feet; the ramparts, parts of the ditch, and other portions may be distinguished. A Roman road called the Doctor's Gate runs from Melandra Castle to Brownsea.

GLOSSOPORIS, a genus of Animals belonging to the order Annelida, and placed commonly near the Leeches. It has a posterior disc, but it is not enterolitiferous.

GLYPTODON (Emmel, T.); GYPTODON, GLYCERIN (Curry, S.); TETES, OROANTO, S.1.)

GLYCERIN, a genus of Dorsibrachiate Annelida. It is distinguished by the form of its head, which terminates in a conical flaky horn-like point, which is divided at the tip into two stout and minute tentacles.

GLYCERYLE. [Chemistry, S. 2.]

GLYCOSINE. [Chemistry, S. 2.]

GLYPHYSODON, a genus of Acanthopterygious Fishes belonging to the family Scissurens. The gill-covers are entire, and they have a single row of tranchets and sometimes notched teeth. The species are found in the Atlantic, but are more abundant in the Indian Seas.

GLYPTODON (Owen, so named from the fluted character of its teeth), a genus of extinct Fossil Animals belonging to the order Edentata, and allied in structure to the modern Armadillos. The first notice of the discovery of the remains of a large edentate animal, similar to that of the Armadillos, was given by the late Sir George Owen, in his paper on the Megatherium, in the 4th edition of the 'Ossianic Fossiles,' published in 1823. This notice occurs in an extract from a letter addressed by D. Danisio Larramag, cure of Monte Vione, to M. Auguste St-Hilaire. The facts stated in this letter are as follows:--A femur was discovered in the Rio del Llanco, branche du Sanlis Grande, which weighed 7lbs.; it was short, but might be from 6 to 8 inches in width; it resembled in every respect the femur of an Armadillo, and bore the impression of bony armour, of which the remains was to send one of the component pieces to M. Auguste Geoffri. The tail was very short and very stout; it had in like manner a bony armour, but this was not verticillate or disposed in rings. These fossils were stated to have been met with near the surface of the earth, in alluvium or strata of transport, indicative of a very recent epoch. Similar fossils are said to occur in analogous strata near the Lake Nirum, on the frontier of the Portuguese colonies.

Requirements for a specimen to belong to the Megatherium, and Cuvier does not appear to suspect that they belonged to anything else, as he merely remarks that the Megatherium had pushed its analogies with the Armadillos so far as to fill up the same band with them.

Subsequently remains of this kind were sent to England, and in the meantime M. Laurillard and Mr. Pentland, on comparing those with those originally sent to England, came to the conclusion that they belonged to the genus Glyptodon. This however was doubted by Mr. Cuff and Professor Owen, seeing that the conformation of the alveoli of the jaw indicated a dentition differing more widely from that of the existing sub-genera of Armadillos than their respective dental characters differ from one another. It was at this conjuncture says Professor Owen, 'that Sir Woodbine Parham received the intelligence of the discovery of an entire skeleton, covered with its tesselated coat of mail, about 5 feet below the surface, in the bank of a rivulet near the Rio Matanza, about 30 miles from the city of Ayres; and having heard of this remarkable discovery the same time transmitted a drawing or sketch of the whole animal, which has since been lithographed, and one of the teeth of the fossil itself. This tooth Sir Woodbine Parham had purchased, and in his examination of it, he considered it to belong to an animal referrible to the Edentata of Cuvier; but its character was so peculiar that I had no hesitation in pronouncing it to differ from that of any known edentate animal, recent or fossil, and from its internal structure proved it to belong to the Armadillo family; for which I proposed the name of Glyptodon, in reference to the plate or sculpured character of the tooth.'

The Glyptodon differs from the Megatherium not only in the form and structure but in the number of its teeth, which appear to be eight on each side of each jaw, as in the section of Armadillos called Coccoauros by Cuvier. It differs from the existing Armadillos in the structure of the vertebrae; and it is characterized by the sinuosity of the process descending from the Zygom, in both which respects it resembles, and evidently indicates a transition to the Megatherium.

Numerous remains of this curious and interesting animal have been from time to time published; and the characters of the very fine specimen, with the cost of mail almost entire, is to be seen in the museum of the College of Surgeons. Portions of this animal are also to be seen in the collection of the British Museum.

Although, when the remains of the Glyptodon were first brought to Europe, it was not thought improbable that the Megatherium also was enclosed in a gigantic suit of armour, no remains that could be regarded as the tassess of such a covering has yet been discovered. It is always difficult, however, to establish a negative, but the following arguments have been adduced by Professor Owen against this supposition, and will be probably regarded by most naturalists as conclusive.

1. The opinion of Cuvier and Weiss, in favour of the Megatherium being so armed, rests on no better ground than the mere fact of bony armour of some gigantic quadruped and the skeleton of the Megatherium having been discovered on the same river as that of Glyptodon.

2. The skeleton, or its parts which have been actually associated with the bony armour above mentioned, belongs to a different and smaller quadruped.

3. No part of the skeleton of the Megatherium presents those modifications which are related to the support of a bony dermal covering.

4. The proportions of the component tassess of the bony armour in question to the skeleton of the Glyptodon, are the same as those between the dermal tassess and skeleton of existing Armadillos, but are vastly smaller as compared with the bones of the Megatherium.

5. No bony armour composed of tassess, having the same relative size to the bones of the skeleton of the Megatherium, as the Glyptodon and existing Armadillos, has yet been discovered.

6. The skeleton of the Megatherium has never been found associated with bony armour of any kind, neither have its parts been found associated.

(Owen, 'Proceedings of Geological Society,' vol. vii, 2nd series.)

GMELIN, LEOPOLD, was born at Göttingen on the 2nd of August, 1758. This eminent chemist and contributor to the literature of the science of which he was an equally noted exponent was born in Göttingen, where his family had for four generations been actively engaged in the pursuit of chemistry, the medical sciences, and several branches of natural history, and one member of which, if not more, is still so engaged. Among the eminent relatives who have already been noticed in the ' Penny Cyclopaedia,' is Johann George Gmelin, apothecary at Tübingen, who was born in 1764, and died 1726, had three sons, all of whom devoted themselves to chemistry and the allied sciences. The eldest Johann Conrad Gmelin (born 1707) was a physician and apothecary at Tübingen; his grandson, Christian Gottlob Gmelin (born 1792) is now professor of chemistry in the same university. The second is the subject of the article Gmelin, John George. The third son, Philip Friedrich Gmelin (born 1723), succeeded the last-mentioned in his professorship of chemistry and botany at Tübingen, and died there in 1766. His older son was Gmelin, Samuel Gottlieb, and his younger son Gmelin, John Faust, who succeeded him in that chair, and afterwards became professor of chemistry at Göttingen, was the father of the distinguished man we have now to commemorate.

Leopold Gmelin, from 1799 to 1804 attended the Lyceum in that city, and in the summer of 1804, his father's lectures on mineralogy. In the autumn of that year he went to Tübingen, where he practised chemical manipulation in the pharmaceutical laboratory of his near relation, Dr. Christian Osmal (the son of Johann Conrad Gmelin and father of Christian Gottlob Gmelin, both already mentioned), and attended Kilimann's lectures on chemistry. In the autumn of 1806 he returned to Göttingen, where he devoted himself with zeal to all branches of medical science, but especially to chemistry, for which he attended Stromeyer's lectures; he also studied mathematics. After passing a distinguished examination, he went, in the summer of 1806,
to Wurttemberg, and thence to Switzerland, which he traversed in all directions, hammer in hand. From the autumn of 1817 he remained in Tübingen, and set sail for his native city. In 1818 he again went to Vienna, where he visited the hospitals, and carried out, in Jacquin’s laboratory, the greater part of the experiments, which formed the basis of his Doctor-dissertation: ‘On the Black Pigment of the Eye,’ published in 1819, and afterwards in the tenth volume of ‘Gode’s’ journal. He left Vienna in the spring of that year, and went to Italy, where he remained till the spring of 1813, chiefly at Naples, but for some time also at Rome.

The observations and collections made in these journeys supplied the materials of the chemico-mineralogical investigations which formed the subject of his ‘Habilitationsschrift’ or thesis at Heidelberg, ‘On Hauny, and minerals related to it, together with geochemical observations on the montane mountains of Italy,’ published in 1814. On his way back to Göttingen he stayed some time at Heidelberg, where the professor of chemistry, George Sncow, being then recently dead, Gmelin was encouraged to give lectures on that science. Availing himself of the opportunity thus presented, he obtained the ‘venia docendi’ in Heidelberg, spent the remainder of the summer at Göttingen, making the necessary preparations for his new duties, and in the autumn of the same year began his career as an academic teacher in Heidelberg, which he subsequently pursued with zeal and success. Two years after he was appointed extraordinary professor of chemistry in the university. His celebrated ‘Handbook of Chemistry’ was then already begun. In the autumn of 1814 he went to Paris to examine the state of chemical researches in Vaquet’s laboratory. Two years afterwards he married Louise Maurer, the daughter of a clergyman of Heidelberg, and settled there, declaring the appointment of professor of chemistry at Berlin, whither he was invited in 1817, to be a great sacrifice. He returned to Göttingen in that year. He was soon afterwards made ordinary professor of medicine and chemistry at Heidelberg. In 1835, he declined an invitation to fill the chair at Göttingen, preferring to remain in his adopted home, although his residence there of more than thirty years would have been either at Göttingen or at Berlin. In the latter portion of his life he was so completely engrossed with the gigantic labour of preparing the fourth edition of his ‘Handbook,’ that he became quite neglectful of his health. In 1848, he had an attack of paralysis, which, though it only deprived him for a while of his power of action, destroyed the freshness and vigour of his manner, and elastically of his spirit. But he still worked at his ‘Handbook’ with untiring industry, and it was by such labours that his power, both mental and bodily, rapidly declined; an insidious disease of the brain was steadily gaining ground. In the spring of 1853 it became evident that his end was approaching, and he died on the 19th of April, in the sixty-fifth year of his age.

Leopold Gmelin’s original researches in chemistry are numerous; they are all of high character, and as complete as the means of investigation existing at the time when they were instituted would admit. In 1820 he undertook, in conjunction with Tiedemann, a series of experiments on digestion; and in 1826 and 1837 these two philosophers published their celebrated work, entitled ‘Die Verdaunung und Harnentwurf.’ But the greatest work to which he contributed to science,—‘a service in which,’ in the words of his friend and patron, ‘the society of St. Antony,’ ‘he surpassed all his predecessors and all his contemporaries’—consisted in the production of his ‘Handbuch der Chemie,’ the beginning and later progress of which have been described in the preface of this work. The first volume of his ‘Handbuch der Chemie’ (Series 1., Vol. 1., pp. 116, 1853) has been published, and is a work of much utility. Gmelin was elected a member of the Russian Academy of Sciences in 1823, and was awarded a medal by the Society for the Promotion of Useful Arts. He was also a member of the Royal Hungarian, Bohemian, and several other Learned Societies.

Gmelin’s ‘Handbook’ of chemistry, moreover, has often directed attention to deficiencies and contradictions in existing chemical knowledge, and has thus given rise to new investigations. It has also been useful in promoting an accurate knowledge of chemistry, not only in Germany, but wherever the science is cultivated. The first edition, which appeared in the years 1817-1819, included in a comparatively small space the extent of chemical science then known; the fourth, which was last prepared by Gmelin himself, was published from 1843 to 1858, and comprehends inorganic chemistry, but, unfortunately, only a small part of organic chemistry. From this the English edition, now in course of publication under the auspices of the Chemical Society, by the late Mr. Henry Watts, R.A., Fellow of the Chemical Society of London, of whose ‘Quarterly Journal’ he is also the editor. The additions made by him bring the ‘Handbook’ down to the existing state of chemical science. Dr. Thomson, desiring to make this work generally available to British chemists, was one of the motives which originally contributed to the establishment of the Chemical Society. The first volume was published at the end of the year 1848; the eleventh, forming the present ‘Handbook,’ appeared in 1857 (November). The translation is continued from a new German edition.

In the ‘Annals of Philosophy’ for August and September 1816, (Series 1., Vol. 1., pp. 116, 1853) a few months after its publication, Dr. Thomson published satisfactory abstracts in English of the Geological and mineralogical portions respectively. Of his dissertation on the black pigment of the eye, Dr. Thomson gave a short account in the same work for January 1818 (Vol. 7., p. 44.) in which Gmelin’s examination of the link of the cuttle-fish, which he had found to possess nearly the same properties with the black pigment, is compared with Dr. Prout’s, then recently published.

[Note: The rest of the text is not transcribed due to the limitations of the task.]
own productions, and it is said that in composing a dialogue, it is his habit to write letters to letter before committing them to paper, by means of which he ascertained more satisfactorily if they were in complete consonance with what the character and situation required. He soon tried his powers in the drama, and his comedy of 'The Reviewer' was highly applauded. As an expert reviser in Russia is the title of a high government officer dispatched to a province to ascertain and report on the character of its administration. The plot and the moral of the play, is, that an impostor who makes his appearance at a provincial town, where he is to be the judge in a case, but has to leave the town. The Russian liberal party, which affixed to it a deeper significance than to a foreigner appears altogether just, and considered it an open and serious attack on the institutions of Russia in general. That it was not lost upon this light by the government seems sufficiently proved by the appointment of Gogol as professor of history at the University of St. Petersburg, where it was his intention to devote himself to more serious studies. His next work however was a dramatic production, 'The Dead Souls' ('Pokinokhodniya Chichagova ila Mertvuiya Dushi'), published at Moscow in 1842. The English public has an opportunity of forming an estimate of this, the principal work of Gogol, as an English translation of it appeared in 1842, entitled 'The Dead Souls.' The author, 'Noble,' falsely declared in the preface to be an unpublished novel, originally written by a Russian in the English language. The style of the English version is indeed remarkable good; but the main strength of a novel lies in the plot and characters. The hero of 'The Dead Souls,' like the hero of 'The Revisor,' is a daring impostor, who goes about to a number of country gentlemen to persuade them to sell to him the land of their estates, which they are technically called in Russia, their 'dead souls,' for the purpose of obtaining an advance from government as the proprietor of a certain number of serfs—the names of the dead not being for a certain period struck off the records. Some of the characters introduced in the tale are certainly sketched with vigour, but in no other production of Russian literature is the foreign reader so much at a loss to detect the charm which has excited the enthusiasm of the native critics. The praises which were lavished on the original may be suspected of having their origin partly in political feelings.

Soon after the appearance of the book which raised his fame to its highest point, the author, whose health was bad, obtained leave of absence, and never returned to Petersburg until the time of the publication of 'Select Passages from N. Gogol's Correspondence with his Friends' ('Vulbramyinya Miesta a Perepikti i Druzami'), St. Petersburg, 1847, 8vo. From the height of popularity this publication sunk him at once to the lowest depths of contempt. His liberal friends found with surprise that the satirist of Russia, when at home, had become the panegyrist of Russia, autocracy and all, when beyond the frontier. Belinsky, who was one of the principal, attacked him fiercely in the 'Sovremennik,' one of the leading reviews in St. Petersburg, in an article which could hardly have been expected to pass the censorship. Gogol addressed him a letter of remonstrance, protesting that the change which had taken place in his opinions was the result of conviction produced by reflection. He describes himself, why the laying of a cornerstone, had himself obtained permission to leave Russia, addressed to him from his sick bed at Salzbrunn one of the most terrific hurling letters to be found in the whole annals of literature, and which was first printed, with the name of the author, 'Zrieds,' or 'Polar Star,' a Russian periodical issued in London in 1855. "Yes," explains Belinsky, "I loved you with all the passion with which a man warmly attached to his country, can love its hope, its honour, its glory, one of its great passions; in the path of self-communis, development, and progress. You had good cause indeed to be shaken out of your repose of soul, for a minute at least, when you lost the right to such love as this. I do not speak thus because I consider any feelings of mine an adequate recompense for such genius as yours; but because in this respect I do not stand alone, but represent a multitude of whom neither you nor I have been the majority, and who have never seen you." "Yes," replied the author, the friend of the Revisor and the Dead Souls,—can you, sincerely, and from your soul, raise a hymn of praise to the disgusting Russian clergy, placing it immeasurably above the clergy of the Roman Catholic Church?" 'The other' was sometimes something, while the former was never nothing but the lackey and slave of the secular power; but is it possible you do not know that our clergy stands in the lowest degree of contempt with Russian society and the Russian people? The clergy of the other Church, and every Russian the representative of gluttony, meanness, servility, impudence! . . . . I will not dilate on your diatribes about the bond of affection between the Russian nation and its rulers. I will only say that this diatribism was met with restraint, and that for the present eyes of persons who in other respects are very close to you in the direction you are taking, I leave it to your conscience to intoxicate itself with the divine beauty of Antichristy; only continue to have the good sense to reserve from it any reasonable distance,—when near, it is not so beautiful, and is apt to be dangerous. . . . You placed yourself too high in the opinion of the Russian public for it to be able to believe in the sincerity of such convolutions as this. What poet, what novelist, what editor, may seem more Russian than Gogol? By your gestures, your 'Noble,' you make your self-consciousness, which is, according to the Russian idea, the man of genius." Belinsky goes on to accuse him of views of personal ambition, and touches with bitterness on a passage in the 'Perepikti,' in which Gogol had appeared to speak with humility of his own works, and to intimate that he did not consider them as forming 'dead souls.' "You have made more noises with your publication than the case required; but after all, their enthusiasm sprung from so pure and noble source that it is impossible to regard them altogether unbecoming in you to surrender them up in the face of their enemies and yours, and to accuse them into the bargain of attributing a wrong meaning to your productions." The reply of Gogol to this bitter dictate is singular, "God knows," he writes, "there may be some truth in whatever you say, and it may be an established truth—that I do not know Russia—that much has been changed in it since I left, and that I must almost begin to study it anew to know it now. The inference I draw from this for myself is, that it behoves me not only not to print new sketches of life, but even two lines on the subject till I have returned to Russia, have seen it with my own eyes, and touched it with my own hands." Neither Belinsky nor Gogol ever returned. Belinsky died in France in 1848, after the Russian revolution of February 1848 had hailed as the dawn of an era of liberty, and Gogol, whose last letter is dated from Oterden, in August 1847, soon followed him. His death is repeatedly alluded to in recent Russian publications, but we have not seen its real date stated.

GOLD, a metal so remarkably from other metals, with a very few exceptions, in the fact that it is found in nature in its metallic state. It is occasionally found mineralised by tellurium. Native gold is Monomeric, and occurs in cubes without cleavage, also in grains, thin laminae, and masses, sometimes biform or reticulated. The colour varies in shade, sometimes being a bright yellow, at others almost silver-white, from the quantity of silver with which it is mixed. It is very ductile and malleable. Hardness 2 ½ to 3. Specific gravity 18 to 20. It varies according to the metals alloyed with the gold. Native gold usually contains silver, and in very various proportions. The finest native gold from Russia yielded—gold 98-96, silver 0-16, copper 0-85, iron 0-08; specific gravity 19-99. At Columbus, 1849, discovered and only 45 per cent. of gold, with 26-45 per cent. of silver; specific gravity 12-666. This last is in the proportion of 3 of gold to 1 of silver. The following proportions have also been observed:—39 to 1, 3 to 1, 6 to 1, 5 to 1 and 1; and this is the most common; 12 to 1 also commonly found.

Copper is often found in alloy with gold, and also Palladium and Rhodium. A Rhodium Gold from Mexico gave the specific gravity 18-6 to 18-8, and contained 34 to 43 per cent. of rhodium. Iron pyrites are often found in alloy of gold by those inexperienced in ores. Gold is at once distinguished by being easily cut in slices and flattening under a hammer. The pyrites when powdered are reduced to powder; iron pyrites is too hard to yield at all to a knife, and copper pyrites affords a dull greenish powder. Moreover the pyrites
give off sulphur when strongly heated, while gold melts without decomposition.

Native gold is in a large extent obtained from alluvial washings. It is also found disseminated through certain rocks, especially quartz and talcose rocks, and is often contained in pyrites, constituting the amorphous pyrites; the detritus affording gold-dust has proceeded from some gold-bearing rocks.

Gold is widely distributed over the globe. It occurs in Brazil (where formerly a great part of that was obtained), along the chain of mountains which runs nearly parallel with the coast of Vila Rica, and in the provinces of Minas Geraes; in New Granada, at Antioquia, Choco, and Grion; in Chili; sparingly in Peru and Mexico; in the southern part of the United States. In Europe it is most abundant, in Hungary, in the Alps, in Switzerland, and in the Pyrenees in Transylvania, at Kapnik, Vorospatak, and Offenbanya; it also occurs in the sands of the Rhine, the Renois, and the Aar; on the southern slope of the Pennine Alps, from the Simplon and Monte Rosa to the valley of Aosta; in Piedmont; in Spain, formerly worked in Asturias; in the county of Wicklow in Ireland; and in Sweden at Edsfors. In the Ural Mountains there are valuable mines, also in the Caucasus Mountains in Little Tibet. There are mines in Africa at Kordofan, in the Sahara, in the western part of Africa from Senegal to Cape Palmas; also along the coast opposite Madagascar, between 25° and 23° S. lat., supposed to have been the Ophir of the time of Solomon. Other regions in which gold is found are the same as in Japan, Formosa, Ceylon, Java, Sumatra, and the Philippines.

Until lately nearly all the gold of commerce came from Asia. Russian and Mexico, but recent discoveries of gold in California and Australia have opened new and vast sources of supply.

From 1600 to 1700 the entire supply of gold for Europe was obtained from America, whose mines are estimated in the one hundred years to have produced 337,500,000l. worth of the finest metal. During the 18th century the supply of gold and silver was still mainly derived from the Americas, the great mine of Valenciana producing 125,000l sterling per annum for 40 years, and the district of Zacatecas adding largely to the amount, although these were rapidly falling towards the end of the century. A great increase of gold was produced from the mines of Russia, which are still very productive; they are principally alluvial washings, and these washings seldom yield more than 52 grains of gold for 4000 lbs. of soil, never more than 120 grains. The alluvium is generally most productive where the loose material is more feruginous. The mines of Ekaterinburg are in the parent rock—a quartz constituting veins in a half-decomposed granite called Beresite, which is connected with talcose and chlorite slates. The sands are deposited in the bottoms of the rivers, seldom below 25 feet, and hence lateral galleries are run to the veins. These mines afforded between the years 1725 and 1841 6799 pounds of gold, or about 30,000 lbs. try. The yield of the mines in pounds of gold was 1842, 970 pounds of gold, or 42,000 lbs. try, half of which was from Siberia, east of the Ural. In 1843 the yield was nearly 60,000 lbs. try; in 1845, 69,000 lbs. try; and in 1846, 75,350 lbs.

In the five following years to 1851 nearly 296,632 lbs. try, weight of gold have been raised in Russia.

At the Transylvania mines the gold is obtained by mining, and these mines have been worked since the time of the Romans. The annual yield of Europe exclusive of Russia is not above 350,000 lbs. try. The sands of the Rhine, Rhad, and Danube are full in small quantity, and the sands of the richest quality contain only about 56 parts of gold in 100,000,000. Sands containing less than half this proportion are worked. Africa yields annually at least 40,000 lbs. try, and Southern Africa 1250 lbs. Try. For an account of the gold-region and gold-produce of California, see California, S. 2.

From November 1850 to June 1851 the Bank of England issued 9,500,000 sovereigns, being at the rate of 18,000,000 a year, and so great is the increasing demand for gold coins, that the Bank was scarcely able to satisfy it.

It may be interesting to know, that from the account kept at the Bank when the light coin was called in, in 1842, that 12,000,000l. were received light, and 36,500,000l. still circulated. 20,000,000l. may be regarded as the proportion of gold coin in circulation, allowing 5 or 3 per cent. for the national wear of the coin.

In the year 1856 there were coined at the royal mint 4,506,100 sovereigns, and 2,951,300 half-sovereigns; total 7,457,400l.

A large quantity of gold is consumed every year in arts and manufactures, and thus generally removed from the stock of our circulating wealth. In Birmingham not less than 1000 oz. of fine gold are used every week, and the weekly consumption of gold leaf is as follows:

<table>
<thead>
<tr>
<th>Country</th>
<th>Gold Leaf Consumption</th>
</tr>
</thead>
<tbody>
<tr>
<td>London</td>
<td>400</td>
</tr>
<tr>
<td>Edinburgh</td>
<td>35</td>
</tr>
<tr>
<td>Liverpool</td>
<td>15</td>
</tr>
<tr>
<td>Manchester</td>
<td>40</td>
</tr>
<tr>
<td>Dublin</td>
<td>12</td>
</tr>
<tr>
<td>Glasgow</td>
<td>6</td>
</tr>
</tbody>
</table>

Total 584 weekly.

Of which not one-tenth can be recovered. For gold leaf use by the electrotype and the water-gilding processes, not more than 10,000 oz. of gold are required annually. One establishment in the Potteries employs 3000l. worth of gold per annum, and nearly 2000l. worth is used by another. The consumption of gold in the Potteries of Staffordshire for gilding is about 3000l. a year, and the paper dressing yields a rose-colour from 7000 to 10,000 oz. per annum.

The Indus and the Emperors were in the earliest ages the earliest spot which man obtained the precious metals, gold—Nubia and Ethiopia on the south, and Siberia in the north next open out to this precious treasure. The marriage of a prince of India to a princess of Persia was at this time a badge of wealth and high rank, and may be regarded as a badge of high rank, and in-viding human luxury. Europe then began to unfold her golden stores, and Illiyria and the Pyrenees, together with the land of the Hungarians and many parts of Germany to the Rhine, were sought successively for gold. Our islands yield little to the store, and the then New World of the Americans opened by Columbus a source from which the Old World was to supply its golden waste. On and on westward rolled the golden ball, until at length it rested in California, and the Aztec rush, equally to that seen El Dorado, and the man of China is found at the side of the English gold stream. Then, as if to double the girdle, the islands of the Pacific and our own Australia open their exceeding stores.

Australia is undoubtedly the most important gold-bearing district in relation to Great Britain. Her shores are now being crowded with emigrants from the mother country seeking the precious metal, and in proportion to her population she is now undoubtedly, in this point of view, the richest country in the world. [Australia, S. 2; Emigration, S. 2.]

For the purpose of guiding those who are seeking Australia on account of its gold, the professors of Natural Science, in the Museum of Practical Geology, delivered a course of lectures in the course of the past winter, the lectures were as follows:

1. 'The Geology of Australia, with Special Reference to the Gold Regions,' by J. Beete Jukes, M.A., F.G.S., Local Director of the Geological Survey of Ireland; author of Sketch of the Physical Structure of Australia.

2. 'On our Knowledge of Australian Rocks as derived from their Organic Remains,' by Edward Forbes, F.R.S.

3. 'The Chemical Properties of Gold, and the Mode of Distinguishing it from other substances resembling it,' by Lyon Playfair, C.B. F.R.S.

4. 'The Dressing or Mechanical Preparation of Gold Ores,' by W.W. Smith, M.A., F.G.S.

5. 'The Metallurgical Treatment and Assaying of Gold Ores,' by John Percy, M.D., F.R.S.

6. 'The History and Properties of Gold,' by Robert Hunt, Keeper of Mining Records.

We subjoin an account of the antiferrous rocks of Australia from the lecture of Mr. Jukes:

In Mr. Arrowmith's map, referred to the Parliamentary Report just issued, all the antiferrous spots are marked in yellow. They occur at intervals along the flanks of the Great Eastern Chain, or on its lateral spurs and subordinate ranges through an extent of country about 1000 miles in length, and as far to the south from London as to the coasts of Turkey, or as from London to Iceland in a straight line. The principal localities marked on this map are Glinton Range and Burnet River, north of the Condamine; Stanley Creek and Canning Downs in the Moreton Bay District; several spots in the neighbourhood of Liverpool Plains; the Turon and Conobolas on the Macquarrie, below Bathurst; the Abercrombie River at the head of the Lachlan; some spots...
on each side of Breadalbane Plains; the Braidwood and Arden diggings in the Shoalhaven district; Lake Eimee in the Australian Alps; and Ballarat, and Mount Alexander and Stawell, to the west of Port Phillip.

"In every one of these localities granite and metamorphic rocks occur, and quartz veins are frequently spoken of. This is an important fact to bear in mind.

"In scarcely any of them do we find mention made of the gold, although it is present, but in the drift clay, sand, and gravel, or lying loose on the surface of the ground. The kilometres of gold, indeed, found by Dr. Ker, north of Ballarat, is described as a block of highly auriferous quartz, lying and consolidated, evidently derived from a broad quartz vein running up the hill behind them. Such a mass, indeed, could hardly be transported far from its original site by any conceivable current of water.

"The superficial drift in which the diggings have been carried on varies in thickness from a few inches to 30 or 40 feet. The following is an extract from a letter given by a Mr. Gibbon, in Melbourne, and reported in the "Melbourne Argus", giving an account of the Ballarat diggings as—: On the surface of the earth was tief in a layer of about a foot thick, below which was a layer of rich black alluvial soil, and below that grey clay; below that again was a description of red gravel, which was sometimes very good; then red or yellow clay, in which gold was found; and then a stratum, varying in its thickness, of masses of those colours, and scarcely worth working; and the next stratum was of hard white pipe-clay, which was a decided barrier. Immediately above it was a thin layer of chocolate-coloured clay, tough and asopy. This was the celebrated blue clay, and was the source of the gold.

"The ground on which the diggings were situated was a sloping bank. The blue clay is found near the surface on the brow of the hill, that is, at the depth of about a foot; but its mass requires to dig 30 feet before arriving at it."

Mr. Labrooke, governor of Victoria, describes the Ballarat diggings as carried on through—

2. Streaked yellowish and red clay.
3. Fine gravels and pebbles, all transported in by the drift clay, and of a very fine gravel, that may be of use to those intending to emigrate there.

"In conclusion, I may perhaps be allowed to utter one word of advice.

"Gold-digging is very hard work—just such work as you see navigators at in a railway cutting, or brick-makers in a brick-pit. You must work hard all day, lie hard all night, with but little shelter, often with scanty food, and with nothing of what you have probably been accustomed to consider necessary. If you find you have no luck at the diggings, or if your health, or strength, or resolution fail you, do not give up or despond altogether. You go out to dig for gold; do not be ashamed to dig for anything else. Speak to those now who have been heathen massacred to mankind without labour. Recollect, it is the avowed object of your voyage, and the only thing you have to trust to. If you fail in digging gold there are lands to be ploughed, sheep to be tended and sheared, cattle to be raised, corn to be sown and tilled, a trade in one of those fully as honourable occupations as digging for gold. The gold, however, has been the result determined to get your living by the strength of your own arms and the sweat of your own brow; and be assured that industry and perseverance lead to fortune in Australia with very little uncertainty in the way than in any part of the world.

Since the above was written, other districts in Australia were yielded the precious metal, and every day is adding to our knowledge of the wide extension of this metal on the surface of the earth.

GOLD COAST COLONY. The Gold Coast is part of Upper Guines, but its boundary is not exactly determined. Geographers state that Cape Three Points (2° 20' W. long.) constitutes its northern boundary; but our navigators extend it farther west to the small river Afromous, which is nearly 70 miles E. from Cape Laho. On the east, the eastern mouth of the river Lagoe (4° 20' E. long.) is generally considered as constituting its boundary towards Benin, though the mouth of the Togo river is more distinguished by the name of the Slave Coast. In the interior are several fertile kingdoms of the Ashantees and Dahomey, on which most of the small states along the coast are dependent. According to the district, the coast is one of the most beautiful, and when the territory under British protection is to include about 8000 square miles of country, with a population of about 400,000. In a dispatch of April 18th, 1853, however, Governor Hill states that he considers his previous estimate of the population to be exaggerated, and that it is probably not more than 300,000. The revenue of the colony is derived from a government grant of 4000l. per annum, a duty of half per cent. ad valorem on all imports, and certain small fees. The income for 1853 amounted to 12,332l., the expenditure to 12,045l. The value of the imports for the year 1853 amounted to 60,000l.; the value of the exports for the same year amounted to 115,000l. The imports for 1854 amounted to 70,000l., and the exports for the same year to 200,000l. The chief articles of export are palm oil, gold, and ivory; they give in exchange fire-arms, iron, and iron-ware, tobacco, rum, Manchester cottons, and some other articles.

The whole of this coast being near 5° N. lat., is considered one of the hottest countries on the globe; yet the mean temperature is only 78°, and in the cold season the thermometer sometimes falls to 75° or 74°. During the Hamatson season, from the middle of December to March, which is the driest and coolest, the air often remains for weeks at 6° to 8° above zero, the thermometer being in some places as low as 17° below zero. The inhabited coast is constantly exposed to the gales and storms that prevail on the north-east. The great rainy season begins in March, and continues to the beginning of June. From June to the end of September is the warm season, which is the most unhealthy, the temperature being 85°, and occasionally a degree or two than at other times, and generate fever. In October and November showers of rain are frequent. Except during the Hamatson season, the winds blow from the west in the middle of the day, from 11 to 3 o'clock, but in the evening from south-west, and in the morning from north-west. The climate is in general unhealthy, especially to Europeans on their arrival. Every person is attacked by a fever, which is called the season. This fever in many instances proved fatal; but it is at this time that the administration of quinine has been found exceedingly useful in promoting the recovery of persons attacked by the fever.

Cape Coast Castle is the principal English fortress; it is situated in 5° 51' N. lat., 1° 18' W. long., and covers a considerable area. In it are apartments for the officers, and barracks for the private soldiers. There are some spacious warehouses. It is built on a rock close to the sea. Near it are the small outposts called Fort William and Fort Victoria. The town which is behind the fortress, is of considerable extent; it has about 10,000 inhabitants, and about 20 are Europeans. The streets are regularly arranged, but the houses are of mud, and huddled together. Within Cape Coast Castle is a government-school, which in 1822 was attended by 150 boys.

The other forts are Accra, Annamaboe, and Discove. Fort St. James at Accra is occupied by a small garrison. The native population is stated to be about 3000. The fort is situated on the coast in 5° 32' N. lat. 0° 12' W. long., and the station is regarded as among the most healthy. The Gold
Coast. Two insurrections occurred at Accra in 1854. Service measures were then resorted to, and the second insurrection, near Accra, was the Dutch fort of Crevecoeur. About 3 miles E. from Accra is the fort of Christianborg, and about 30 miles N.E. from Accra is the fort of Fredensborg, both recently purchased from the Danes by the British government. The purchasing power on this occasion consisted, besides arms, gunpowder, spirits, and wines. Accrabeo has been noticed separately. The population is said to be about 4500.

The exports include the articles usually sent from this coast, namely, palm-oil, gold-dust, ivory, and grains, and the imports likewise. The trade is an entrepôt of commerce for Ashantee and the interior. Accra is situated in 4° 48' N. lat., 1° 47' W. long. The native population is said to consist of vessels of 100 tons in their cargoes. The native population inhabiting the town is about 1800.

The introduction of civilizing influences to the native population of the Gold Coast, is chiefly owing to the labours of the Wesleyan missionaries. From the despatches of successive governors of the colony, addressed to the Secretary of State, it appears that considerable progress has been made in communicating to the natives the benefits of an educational and industrial training. In the year 1832, the population of the Gold Coast was stated at 6000 persons, and about 1200 children were in attendance at the schools of the mission. Mr. Freeman, the missionary superintendent, established in 1831 an industrial school and gave Demonstrations of the art of making Iron, Castle. In February 1852 there were 28 native youths under training at this establishment. On December 31st 1852 Mr. Freeman, writing to Governor Hill, says, "We have now about 750 wines and 6000 coffee-plants. The roads in the establishment, are being worked, and believe there it is well. The Missionary Society expends about 500L. a year on the Gold Coast Mission. Among other evidences of advancing civilization may be noticed the erection by the natives of many new cottages for the residence of the missionaries. This is the first sign of the native's aspirations to the amenities and comfort of civilized life. European dwellings, and the construction of several good roads to facilitate communication between the towns and villages in the interior. The roads have been constructed voluntarily by the natives under the direction of the missionaries. These encouraging features have been more particularly noticeable in the neighbourhood of Abakrampa, the capital, and Domonei, the second town of the Abrab tribe and district, in the Cape Coast territory. In some of the principal towns of the interior, the houses for Christian worship have been built by the chiefs at their own expense.

Governor Hill has endeavoured to enlist the sympathies and co-operation of the native chiefs, by forming them into a body of the highest authority, including a council, with an executive at its head. Each chief has agreed to pay a poll-tax of Ls. yearly for each person belonging to his tribe: from the fund thus provided each chief is to receive a stipend to support the dignity of his position, and from it is to be defrayed the cost of such general measures of improvement as the legislative body may agree to undertake. Besides the school at Cape Coast Castle, already noticed, the Governor has recently established one in the interior, which in April 1853 had 54 scholars, and proposes to establish schools at such places within the range of his government as have not been already supplied by the Wesleyan body. He has also employed the natives composing the Gold Coast corps, numbering 335 non-commissioned officers, rank and file, engaged in the work of polishing, giving them the opportunity of attending the regimental school when they can be spared from other service. In this way many members of the corps have made considerable progress in reading, writing, and a knowledge of the mechanical arts. By their labours 40 miles of a military road has been opened through the Assin country, directly into the interior towards the capital of Ashantee; and a fine carriage-road to Accrabeo was in process of construction in April 1853. On this road a large number of natives have been employed, and at the entrance to the town, the granite for which had been first quarried by the soldiers from a deposit opened by them in the immediate neighbourhood.
